ARTICLE INFO

ABSTRACT

The aim of this study was to detect extended spectrum β-lactamase (ESBL) in bacteria isolated from urine collected from urinary tract of infected pregnant women. A total of 100 midstream urine samples were collected from Omdurman Military Hospital from April to May 2013. Specimens were cultured onto cysteine-lactose-electrolyte-deficient (CLED) agar to identify urinary tract infection (UTI) causative bacteria by colonial morphology, Gram reaction and conventional biochemical tests. Out of 100 urine specimens; 56 (56%) of samples gave significant bacterial growth (the Gram negative bacilli were 42 (75%). The most frequent Gram negative were Klebsiella oxytoca 15 (26.8%) and Escherichia coli 10 (17.9%), while the most abundant Gram positive was Staphylococcus saprophyticus. In The susceptibility test, 5 isolates were resistant to 3rd generation cephalosporins (ceftazidime, ceftriaxone and cefotaxime) as follow: 2 K. pneumoniae, 2 E. coli and 1 Proteus vulgaris. ESBL production test done for all bacterial resistance to 3rd generation cephalosporin and then confirmed by combination test by using Double disc synergy test 5 (11.9%) isolates gave positive result. The PCR was done for 5 isolates using TEM, SHV, and CTX-M primers. TEM gene was the most predominant one followed by CTX-M and the least one was SHV gene. From the results it could be concluded that these genes are responsible for the resistance of cephalosporins.

KEYWORDS:
ESBL bacteria, urine, pregnant women

INTRODUCTION:

Extended spectrum beta lactamases (ESBL) producing organisms are emerging pathogens with greatest spread in general population, and their presence in clinical infection can result in treatment failure when using 3rd generation cephalosporins (Paterson and Bonomo, 2005). The extended spectrum β-lactamases are enzymes
elaborated by some bacteria and responsible for their resistance to extended spectrum 3rd generation cephalosporins e.g. ceftazidim, cefotaxime, ceftriaxone and monobactam e.g. azteronem (Carlos, 2000). These enzymes catalyze the hydrolysis of the β-lactam ring of antibiotics; ESBLs have been reported worldwide in many different genera of Enterobactericeae, Pseudomonasaeruginosa, (Friedman et al. 2008). Klebsiella pneumonia and E.coli in addition N. gonorrhoea (Agrawaletal., 2008). ESBL producing organisms are often resistant to several other classes of antibiotics, as the plasmids with the gene encoding ESBLs often carry other resistance determinants; initially ESBL producing organisms were isolated from community (Pitout and Laupland, 2008). The ESBLs are mediated by bla TEM, bla SHV and bla CTX-M genes in Enterobacteriaceae and other Gram-negative bacteria, numerous molecular typing methods have been developed for their identification. The multiplex PCR assay allowed the identification of bla TEM, bla SHV, and bla CTX-M genes in a series of clinical isolates of Enterobacteriaceae with previously characterized ESBL phenotype (Monstein et al., 2007). The first plasmid β-lactamase TEM1 was described in Germany 1980, and in France 1985 (Perez et al., 2007). The National Committee for Clinical Laboratory Standards (NCCLS) recommended that microbiology laboratories reported ESBL –producing isolates of E. coli and Klebsiella species are resistant to all penicillins, cephalosporins and azteronam, irrespective of their individual in vitro test result. Urinary tract infections (UTI) that affect parts of the urinary system occur more in women than men, especially in pregnancy due to the increased risk of kidney infection. During pregnancy high progesterone level elevated the risk of decreased muscle tone of the ureters and bladder which lead to greater likelihood of reflux where urine flows back up the ureters and towards the kidney (Dielubanzaand Schaeffer, 2011) The bacterial spectrum and antimicrobial resistance may vary temporarily and geographically, each institution must undertake its own local evaluation such an evaluation may also be useful to detect emerging trends of antimicrobial resistance (Wagenlehner et al., 2008).

The objectives of this study were to: Isolate and identify the important bacterial pathogens causing UTI in pregnant women. Determine the drug resistance patterns of the isolated bacteria with emphasis to third generation cephalosporins, and Use molecular biology tools e.g. PCR in the detection of ESBL encoding genes.

MATERIALS and METHODS

This work was carried out in Military Hospital in Omdurman, during the period from April to May 2013. Pregnant women showing signs of urinary tract infection (UTI) were included in this study. One hundred mid-stream urine samples were collected. Data was collected using interviewing questionnaire.

Collection of specimens:

Five ml midstream urine samples were collected in wide mouth screw-capped and leak-proof sterile containers containing 0.1g/10 ml boric acid as preservative.

Cultivation of specimens:

The specimens were streaked under aseptic conditions on cystosine- lactose-electrolyte deficient (CLED) agar using sterile standard bacteriological wire loop. The cultured plates were incubated aerobically at 37°C for overnight and observed for bacterial growth.

Identification:

Was done according to the criteria of Cheesbrough (2000)
Colonial morphology:
Used as first identification depending on size, colour, edges, side views and fermentation of lactose.

ESBL screening test:
All isolates (table 2) were tested for their susceptibility to the 3rd generation cephalosporins, i.e.: ceftazidime (30µg), cefotaxime (30µg) and ceftriaxone (30µg) by the standard disc diffusion method as recommended by the Clinical and Laboratory Standards Institute (CLSI) guidelines (2010). ESBL were screened by detection of reduced zones of inhibition around 3rd generation cephalosporins.

The bacterial isolate was considered as ESBL producer when the zone diameter for: ceftazidime < 22mm, cefotaxime < 27mm and ceftriaxone < 25mm. Resistant isolates to at least one of the 3rd generation cephalosporins were checked for ESBL production.

Double disk synergy test (DDST) was performed according to Jarlier et al., (1988). Isolates were inoculated on Muller–Hinton agar plates. Discs containing ceftazidime (30Mg), cefotaxime (30Mg) and ceftriaxone (30mg) were placed 20 mm (centre to centre) away from a disc containing 20 mg amoxicillin/10mg clavulanic acid (AMC). Plates were incubated for overnight at 37ºC. ESBL production was considered positive if the zone of inhibition around one or more of the 3rd antibiotic discs showed clear cut increase towards the AMCA disc (Ananthakrishnan et al., 2000).

Genotypic characterization of ESBL genes
DNA extraction and PCR assay were performed according to the method of Cao et al., (2002)

RESULTS

Out of 100 urine specimens collected from the study population, bacterial growth was obtained in 56 cultures. The results of Gram stain found 42(75%) Gram negative bacilli and 14 (25%) as Gram positive bacteria. The Gram negative was K. oxytoca 15(26.8%), E. coli 10(17.9%), P. vulgaris 8(14.3%), K. pneumoniae 5(8.9%), Citrobacter freundii 1(1.8%), Enterobacter spp. 1 (1.8%), Providencia spp. 1(1.8%) and Serratia marcescence 1(1.8%). The Gram positive Staphelococcus saprophyticus 13(23.2%) and S. aureus 1(1.8). The results of biochemical test for Gram negatives E.coli,
K, P. vulgaris, Citrobacter, Enterobacter, Providencea and Serratia and for Gram positive cocci S. aureus and S. saprophyticus. The antibiotic susceptibility test was found to be that 2(40%) of K. pneumnae was resistant to all antibiotic used (ceftazidime, cefotaxime and ceftriaxone). All K. oxytoca was susceptible to all antibiotic used, 8(80%) of E. coli isolates were susceptible. P. vulgaris 7(87.5%) were susceptible. All S. saprophyticus were susceptible. Enterobacter spp., Providencea spp., Serratia spp., Citrobacter spp. and S. aureus were sensitive to 3rd generation cephalosporins used (table, 2).

The ESBLs producer were screened by resistant to 3rd generation cephalosporins found in 5 (11.9%) isolates confirmed by the using double disc synergy test (DDST). These were found in 2 K. pneumoniae, 2 E. coli and 1 P. vulgaris isolates. The commonest prevalence of ESBL gene was TEM gene in all 5 organisms (Figure, 2). CTX-M was produced by 3 organisms (2 E. coli and 1 K. pneumonia) and SHV gene was detected in 1K. pneumoniae and 1 P. vulgaris (table, 3 and Figure, 2).

In this study out of 100 urine samples examined only 56 isolates gave significant bacterial growth on CLED medium. *K. oxytoca* 15(26%), *K. pneumoniae* 5(8.9%), *E. coli* 10(17.9%), *P. vulgaris* 8(14.3%), *Enterobacter* spp. 1(1.8%), *Citrobacter freundii* 1(1.8%), *Provedencia* spp. 1(1.8%), *S. aureus* 1(1.8%), *S.marcesan*e and *S. saprophyticus* 13(23.2%). In this study, 5(11.9) isolates producing ESBL were encountered, of which 2 (40%) *K. pneumoniae*, 2 (20%) *E. coli* and 1(12.5%) *P. Vulgaris*. These results were similar to the combined disc method currently recommended by the NCCLS (2010). For laboratories that perform susceptibility testing when using disc diffusion, when modified DDST could be easily incorporated in to an already existing system. This finding was in agreement to Omer (2013) in Sudan reported that *E. coli* and *K. pneumoniae* are most ESBL producers. Urine was the main source of ESBL producing isolates, which is in agreement with that found by Akbaret *et al.*, (2007), who reported that (70.4%) of urine was the main source of ESBLs from all patient. The present showed that high prevalence of TEM gene. This was Similar to that reported by Sekaret *et al.*, (2009). The CTX-M was the second ESBL gene detected in this investigation. This finding that was in agreement with that reported by Feizabadi, *et al.* (2010). The present this study showed that CTX-M was most common gene among *E. coli* this was in agreement with that reported by Mirzaet *et al.*, (2006). The SHV gene was the less frequent gene in this study, this result is similar with many reports around the world, such as in Thailand by Kiratisinet *et al.*, (2008) and in Iran (Moosavian and Deiham,Dezfulet *et al.*, 2011). These results were not coinciding with those of Tasli and Bahar(2005) and Ben-Ami *et al.*, (2009), who detected SHV in 74.3% of isolates. This study is also disagreed with that reported in Sudan by Hamedenil and Eltayeb (2012) who found CTX-M is highly prevalent (22.5%) but
agreed with SHV (2.2%) the less gene obtained.

Conclusions

In Sudan ESBL genes were among most strains of Enterobacteriaceae, especially E. coli and K. pneumoniae. ESBL SHV, TEM and CTX-M genes are predominant in Sudan among Enterobacteriaceae isolates. Some strains carried one or more of these genes and this may lead to the resistance to some cephalosporins that might complicate the management of the disease problem.
