ABSTRACT

This study aimed to determine the prevalence of Salmonella spp., E. coli and aerobic plate count in meat products in Khartoum State. Aerobic plate count was used to identify the contamination of the product with pathogenic microbes. A total of 100 samples of meat products were collected from factories and analyzed. The samples included 20(20%) burger, 30 (30%) sausage, 25 (25%) kofta, 12 (12%) minced meat, and 13 (13%) of different type of meat products. Cultural characteristics and different biochemical and serological tests and aerobic plate count were used to detect Salmonella spp., Escherichia coli and aerobic microbial contamination. The results showed that 4 (4%) of samples were positive for Salmonella spp. and 44 (44%) were positive for the presence of Escherichia coli. In addition 71% of samples exceeded the limit (10^5 cfu/g) of the Sudanese Standard for Aerobic Plate count test in meat products. The study concluded that there is contamination with Salmonella, E. coli and there is high total aerobic plates count in meat products in Khartoum state.

INTRODUCTION:
Since Salmonella spp. were first discovered in human tissues in 1880, and then isolated from pigs in 1885 by Salmon (Buxton and Fraser 1977), their significance as important pathogens has been recognized. To date, more than 2,500 Salmonella serovars have been identified (Popoff et al. 2004), approximately 2, 000 of which are capable of infecting humans. Their host specificity may vary even between variants within a serovar (Wall et al. 1995). Epidemiologically, Salmonella bacteria can be divided into human-specific serovars, serovars with host adaptation but also able to infect humans, and serovars able to infect both humans and animals (Jay et al. 2005). Salmonella is a Gram-negative,
rod-shaped belonging to the family Enterobacteriaceae (Marlony et al., 2003). 

Salmonella are facultative anaerobes, flagellated rod-shaped bacteria with both respiratory and fermentative metabolic pathways. They are oxidase negative, ferment glucose and produce acid and gas. The organisms grow on citrate as a sole source of energy. They decarboxylate lysine and ornithine, generally produce hydrogen sulfide, and do not hydrolyse urea. One of the characteristics of this genus is that most members do not ferment lactose or sucrose (Yousef and Calstrom, 2003). Diseases caused most frequently by Salmonella enterica are collectively known as salmonellosis (Yousef and Calstrom, 2003). The disease in humans is generally contracted through the consumption of contaminated food of animal origin (mainly meat, poultry, eggs and milk), although many other foods, including green vegetables contaminated from manure, have been implicated in its transmission.

The majority of pathogens causing foodborne illnesses are considered to be zoonotic (Käferstein and Abdussalam 1999). The increase in international trade in agricultural, aquacultural and manufactured food products has facilitated the spread of Salmonella (D’Aoust, 1994). Salmonella has been the subject of public health concern as an agent causing foodborne diseases for over a century (Hardy, 2004). Salmonella has been estimated to be responsible for 30% of the foodborne outbreaks in the United States (Mead et al., 1999).

Isolation and identification of strains involved is an important step in controlling Salmonella outbreaks or sporadic clinical cases (Threlfall and Forst, 1990; Gonzalez and Mendoza, 1995).

E. coli is a gram-negative, facultative anaerobic, non-spore-forming rod, which belongs to the Enterobacteriaceae family. The odor Escherich first cultured ‘Bacterium coli’ in 1885 from the feces of a healthy individual. It was renamed Escherichia coli in 1919 in a revision of bacteriological nomenclature (Law, 2000). Many benefits have been found from E. coli in human medicine, food industry, and the water industry. Some studies suggest that E. coli can serve as a benefit to the human body by synthesizing vitamin K and by using competitive inhibition to out compete other bacteria that might enter the intestinal tract. Differences between strains of E. coli lie in the combination of different antigens they possess. There are three types of antigens: the somatic lipopolysaccharide antigen (O), the flagellar antigens (H), and the capsular antigens (K). There are approximately 174 O antigens, 56 H antigens, and 103 antigens that have been identified. There are several stains of E. coli that have been isolated. The enteric E. coli are divided on the basis of virulence properties into enterotoxigenic (ETEC), enteropathogenic (EPEC), enteroinvasive (EIEC), verotoxigenic (VTEC), enterohemorrhagic (EHEC), and enteroaggregative (EaggEC).

ETEC can be found in humans, pigs, sheep, goats, cattle, dogs, and horses; EPEC is found in humans, rabbits, dogs, cats, and horses; EIEC and EAggEC are only found in humans; VTEC is found in pigs, cattle, dogs, and cats; while EHEC is found in humans, cattle, and goats and attack porcine strains that colonize the gut in a manner similar to human EPEC strains (Fratamico et al., 2002). Pathogenic Escherichia coli, specifically E. coli O157:H7, has emerged as a foodborne pathogen of great concern in beef
products. While generic *E. coli* is considered a part of the normal microflora in the intestinal tract of most warm-blooded animals, including humans, many pathogenic strains can cause diarrheal disease and have been associated with food-borne illness (Doyle, 1990).

The aerobic plate count is designed to provide an estimate of the total number of aerobic organisms in a particular food. A series of dilutions of the food homogenate is mixed with an agar medium and incubated at 35°C for 48 hr. It is assumed that each visible colony is the result of multiplications of a single cell on the surface of the agar (Andrews, 1992). The total aerobic plate count is useful for indicating the overall microbiological quality of a product and, thus, is useful for indicating potential spoilage in perishable products. The aerobic plate count is also useful for indicating the sanitary conditions under which the food was produced and/or processed (Andrews, 1992).

This study aimed to determine the prevalence of *Salmonella* spp, *E. coli* and aerobic plate count in meat products in Khartoum State.

**MATERIALS AND METHODS:**

This is a descriptive cross-sectional study aimed to detect *Salmonella* spp, *E. coli* and aerobic plate count from meat products in Khartoum State in the period from May 2015 to January 2018 was conducted in the Research Laboratory, Sudan University of Science and Technology.

**Sampling and Sample size:** One hundred meat products samples were randomly selected. Samples were collected from markets and meat factories in Khartoum State. Samples were taken and analyzed in accordance with the International Organization for Standardization (ISO 17604:2003/Amd.1:2009 (E)), (ISO 6579:2002/Amd.1:2007(E)). The media and reagents were used from Oxoid and Mast, UK. All tests were done according to the International Organization for Standardization (ISO 6579:2002/Amd.1: 2007(E)). Twenty-five gram of representative portions of poultry and poultry products was used and kept into a sterile stomacher bag. Then 225 ml buffer peptone water (BPW) was added into the bag and was homogenized, then sealed and incubated at 37 °C for 18-24 hours. Portions of 1.0 and 0.1 ml of BPW pre-enrichment culture were transferred to 10 ml of enrichment in selective broth medium Muller Kauffmann TetraThionate-novobiocin broth (MKTTn), and 10 ml of Rappaport-Vassiliadis medium with soya (RVS broth), respectively. MKTTn broth enrichment cultures were incubated at 37 °C for 24 h. The RVS broth enrichment cultures were incubated at 42°C for 24 h. A loop-full of each enrichment broth were streaked on selective media plates of Xylose Lysine Deoxycholate Agar (XLD) and Bismuth Sulfite (BS) agar. Then plates were incubated for 24 hours ± 2 hours at 37°C. After that plates were examined for *Salmonella*. five colonies suspected were taken for confirmatory test; selected colonies were streaked onto the surface of pre-dried nutrient agar plates and incubated at 37°C ± 1°C for 24 h ± 3 h. Isolated colonies were examined biochemically on Triple Sugar Iron agar, Urea Agar, Voges-Proskauer medium, tryptone/tryptophan medium and 1-Lysine decarboxylation medium. The isolates were further confirmed by slide agglutination test using polyclonal O-, Vi- and H-antiserum.
specific for genus *Salmonella*.  

**E. coli isolation and calculation:** Isolation and identification of *E. coli* were done according to the International Organization for Standardization (ISO 16649-2:2001(E)).

By using of a sterile pipette, 1 ml of the tested sample was transferred to a sterile Petri dish. Initial dilution \((10^{-1})\) inoculated in to two plates, then repeated this procedure with the further

**Counting the colony-forming units:** After the specified period of incubation counting of the typical CFU of glucuronidase-positive *Escherichia coli*.

**Calculation of Aerobic Plate Count (APC):** Calculation of APC was done according to the International Organization for Standardization (ISO 4833:2003(E)).

Two sterile Petri dishes transferred to each one by means of a sterile pipette 1 ml of the tested sample from initial suspension \((10^{-1})\) dilutions. The same procedure was used for the another dilution \(10^{-2}\) then Poured 15 ml of the plate count agar into each Petri dish and allowed to solidify and incubated at \(30 \, ^\circ C \pm 1 \, ^\circ C\) for \(72 \, h \pm 3 \, h\). and colonies counted.

**RESULTS:**

In the present study, a total of 100 samples of meat products were collected from factories and analyzed. The results showed that 4 (4%) of samples were positive for *Salmonella* spp and 44 (44%) of samples were positive for *Escherichia coli*. In addition to 71 (71%) of samples exceeded the limit \(10^5 \) cfu/g of the Sudanese Standard for Aerobic Plate count test (Figure 1). Results of biochemical tests used for identification of *Salmonella* spp. were shown in Table (1).

**DISCUSSION:**
The purpose of microbial testing is to confirm that all possible avenues of contamination have been identified and that these avenues are being controlled (Kvenberg and Schwalm, 2000). Meat samples were selected for this study because they are reported to frequently harbor various enteric organisms. The present study showed that the prevalence of Salmonella species in meat and meat products constituted 4%. These results were in line with the results of others who obtained a relatively contamination of meat and meat products with different serotypes of Salmonella (Campbell and Gilbert, 1995). Salmonella spp. were found in minced meat, kofa and burger (Mohamed, K. 2013). The lowest percentage of Salmonella spp. in our study agree with finding of 4% by (Fatin et al., 2004) and disagrees with obtained by (Essa et al., 2009) which was 23.3%. Escherichia coli and fecal coli forms are considered to be the most important and compulsory measure of microbiological quality of food and food related products in terms of hygiene. Their presence is used as indicators of fecal pollution. Among these, E. coli is often preferred as a more specific indicator of fecal contamination because it is specific and most reliably reflects fecal origin (Feng and Hartman, 1982) and (Doyle and Erickson, 2006). Testing for generic E. coli is one method that is required in meat and poultry processing plants (Eisel et al., 1997).

In this study the over-all prevalence of E. coli in all meat products was 44% which similar with some other studies (Ayla, E and Seza, A 2012). reported the results of microbiological analysis of retail meat samples relative to the contamination levels of Escherichia coli are 53.6%. In Australia, E. coli was detected on 15.4% of meat and meat products samples. In present study, 71 (71%) of samples contaminated with aerobic organisms exceeded the limit allowed by the Authority of Sudanese Standards and Metrology Organization which is $10^5$ cfu/g. The higher aerobic count in meat indicated that sanitary measures during handling, manufacturing process, and packaging were neglected and also low quality of meat was used. The variations in total aerobic count in meat samples might be due to the contamination from equipment or the environment.

The total aerobic plate count is useful for indicating the overall microbiological quality of a product and, thus, is useful for indicating potential spoilage in perishable products. The aerobic plate count is also useful for indicating the sanitary conditions under which the food was produced and/or processed (Doyle, 1990).

The study concluded that there is contamination of Salmonella, E. coli and there is high in total aerobic plate count test on meat products in Khartoum state.
