

Appendix A

The load flow Algorithm in NEPLAN program:

The load flow problem is non-linear, because at every network node i , an apparent power S_i is given:

$$S_i = P_i - jQ_i = V_i \cdot I_i^* \quad (* = \text{conjugate complex})$$

The power Application software (PAS) is driven by off line and on line data, for study purposes, all functions of PAS can also be operated off line.

Given:

a) off line data:

- Elements with impedances (lines/cables, transformer, generators) with limits of operation, these 2 terminal element are represented by their branch four-poles and the individual branch admittance matrices.
- Elements without impedances (bus-bar, circuit breakers isolators, CTs, PTs, etc) with limit of operation.
- Static network: topology (Node-Branch representation, static connection of elements without and with impedances, regardless of the positions of the circuit breaker and isolators).
- Generator and load data: attached to bus-bar node type: PQ, PV, Slack.

b) On Line: data:

- Actual network: topology (position of the circuit breakers and isolators, closed, open running, under-fined etc).
- Actual measuring values: at bus-bars for load flow additionally branch values for state estimation to be calculated:

a) All node voltages, voltage. Vector, vector of state variables define the actual steady state of the system.

b) Results derived from the state vector:

- Branch currents and powers, overload indication.
- Node voltages with indication of limit violation.
- Balances of active and reactive power, active and reactive losses.

Application of the load flow Algorithm:

a) Off line for study purposes:

Function in NEPLAN 2000

b) On-line in PAS (power application software):

- SSE state estimation.
- Optimal load flow.
- CAN contingency analysis etc.

Solution methods:

Overview: Gauss Seidel, current iteration, Newton-Raphson

Gauss- Seidel:

Historical, no inversion of Y matrix needed:

a) Set state vector V to + j0 pu (flat start).

b) For each node i DO:

V i is Calculated, the other Vj remain constant joint solution of:

$$I_i = Y_{ii} * V_i + \sum_{j \neq i} Y_{ij} * V_j$$

and

$$I_i = (S_i / V_i)$$

Special treatment of PV nodes. Slack node:

V_i is not changed

c) The calculation is stopped, if the change of state vector is below a specified accuracy limit:

Much iteration is required, convergence of the iteration process is questionable, but storage requirement are small.

Current Iteration method:

Basic: Factorized, Y – matrix

a) Set state vector \underline{V} to $\underline{1} + j0$ pu (flat start).

b) Repeat until convergence is reached.

b1) for each node i Do:

$$I_i = (\underline{S}_i / \underline{V}_i)$$

Special treatment of PV node. Slack in node: V_i is not changed.

b2) Network solution:

Solution of $V = Z * I$ forward substitution

Result: New state vector V_{new}

b3) Convergence check: the check: The calculation is stopped, if the change of the state vector is below a specified a currency limit.

$$||\underline{V}_{new} - \underline{V}||$$

b4) if convergence not yet reached it

$$V_i = V_{new}$$

b5) END REPEAT.

Just a few iterations are required typically 4...7, even for large networks, convergence is in general reached, if there exists also a physical solution the problem and the static stability limit are not violated.

Newton Raphson:

Principle: minimization of a mismatch function:

Search for the point, defined by the state vector V , where the mismatch function zero.

The mismatch function in our case is the difference between the actual and the given nodal apparent powers:

$$\Delta S_i = S_i^{actual} - S_i^{given}$$

$$S_i^{actual} = V_i^{*} \cdot I_i^{*}$$

Because the I_i depend also from V_i , the first term in the above equation is nonlinear in V_i . All deviations ΔS_i are caused by deviations in the state variables, ΔV_i and we can make a formal linearization a round the working point:

$$\underline{\Delta S}_i = \underline{\partial V_i} / \underline{\partial V_i} = \underline{H}^{-1} [\underline{S} - \underline{A}]$$

This can be illustrated by fig below:

Because the (partial) derivative is not defined for complex numbers all values $\underline{S} = P + jQ$, \underline{V} , \underline{I} , \underline{Z} , \underline{Y} must be broken down into real numbers either in Cartesian or in polar coordinates.

In this case the matrix describing the partial derivatives in $\underline{H}(A)$ is a real matrix with the dimension $2N \times 2N$ and is called it or Jacobian (Jacobi's matrix).

The vectors of power and voltage differences have the dimension $2N$ each.

According to $\underline{H}(A)$ the change of the state vector $\underline{\Delta V_i}$ can be calculated by multiplying the inverse of H , H^{-1} with the given power mismatches S_i .

Discretion of iteration:

a) Set state vector V to $1 + j0$ pu (flat start).

b) Repeat until convergence is reached.

b1) for each node i Do:

I_i by using

$$S_{i\text{actual}} = V_i * I_i \text{ and } S_i \text{ actual} = S_{i\text{given}}$$

$\underline{\Delta S}_i$ by using

$$\underline{\Delta S}_i = S_{i\text{actual}} - S_{i\text{given}}$$

Special treatment of PV nodes slack node:

V_i is not changed

b2) Network solution:

Setup of H and factorization:

for each iteration step or:

set up of H and factorization once at the beginning (constant slope).

Solution of $H(A)$ by forward and backward substitution result new state vector

$$V_{\text{new}} = V_{\text{old}} + \Delta V$$

b3) convergence check: The calculation is stopped if the change of the state vector is below a specified accuracy limit.

b4) if convergence not yet reached:

$$\text{Set } \underline{V}_i = \underline{V}_{\text{new}}$$

b) END REPEAT:

Just a few iterations are required (typically 4.....7, even for large network).

Convergence is in general reached, if there exists also a physical solution to the problem and the static stability limits are not violated.

In order to minimize the calculation burden several treatment of H are in use:

- Decoupled load flow: only the dependence of P on the voltage angles and of Q on the voltage magnitudes is considered.
- H calculated factorized once, only after a certain number of iterations or at each iteration.
- etc. etc.
