Dedication

To my family,

Friends and teachers

Acknowledgments

I would like to first proceed with deep and special thanks to my supervisor, prof. Dr. Nafie. A. Almuslet who was providing his support and his extensive experience to me during this Ph.D. work.

His precious and valuable advices led my steps and enabled us to come up with his humbled Ph.D. research on Leukemia cancer in which I hope to be an addition for those wishing to dig furtherer in this very topic.

I also would like to pass my sincere thanks to Al Amel Teaching Hospital as well as (Radiation and Isotopes Center Khartoum (RICK) Hospital who are enlighten, strengthen, and dedicating their time and support to me upon the past months.

Finally I am running out of words to thank all in this short space that was behind these efforts.

Abstract

In this work Raman and FTIR spectroscopy were used for spectroscopic characterization of leukemia blood samples. Fifteen samples were collected from leukemia patient's types: acute, chronic lymphocytic leukemia and acute chronic myeloid leukemia. The patients were diagnosed by histopathologies in Radiation and Isotopes Center Khartoum (RICK) and Alamal Hospital.

The analysis of the Raman spectra was done for the peaks of proteins: 1240-1310, 1548, 1655, 3200, 3700-3500 and 628 cm^{-1} . These bands are attributed to α -helical of amid I, amid II, amid III, N-H bond of amid A and amid VI, respectively. Also the bands at 1120 and 835 cm^{-1} that are representing the strong C-N vibration bond of ribose and the vibration bond of CH_2 . Raman shift was recorded at wavenumber 1140 cm^{-1} which represents the stretching vibration of amino acid.

The Raman shifts observed in the wavenumbers 2800, 1446 cm^{-1} and 2921 cm^{-1} are attributed to lipids and C-H asymmetric vibration in fatty acid. The Raman shifts observed at 1310 and 1499 cm^{-1} represent the nucleic acid, the band at 779 cm^{-1} represent the CH_2 group of nucleic acid. Spectroscopic differences were noticed between normal and cancer samples using FTIR at (2091, 3450 cm^{-1}) for lipids, (1548, 1650 cm^{-1}) for proteins and (1170, 1303 cm^{-1}) for nucleic acids.

The intensities of leukemia samples peaks are increased compared with the intensities of peaks in normal blood samples recorded by FTIR spectrometer with no difference in position of the absorption lines.

When comparing the two techniques, it can be concluded that the Raman spectroscopy has higher resolution and is more precise than FTIR spectroscopy. Both techniques can be used for diagnosis of leukemia blood samples efficiency.

المستخلص

فى هذا العمل تم استخدام مطيافية رامان ومطيافية تحويلات فوريرير للاشعة تحت الحمراء للتوصيف الطيفى لعينات من سرطان الدم (اللوكيميا). استخدمت فى هذه الدراسة 15 عينه دم جمعت من مرضى مصابين باللوكيميا النخاعية الحاده والمزمنة, واللوكيميا الليمفاوية الحاده و المزمنة. جمعت العينات من معملى امراض الدم بكل من مستشفى الذره بالخرطوم ومستشفى الامل.

اظهرت نتائج هذا الفحص ان هناك ازاحات فى طيف رامان الخاص بالروابط ذات الاعداد الموجية 628, 1240-1310, 1548, 1655, 3200, و 3500-3700 سم⁻¹ حيث تمثل هذه الروابط الاميدات فى البروتين بانواعها المختلفة. وسجلت ازاحات فى منطقة الطيف ذات العدد الموجى 1140سم⁻¹ والتي تمثل الاهتزاز التماثل لرابطة كربون-اوكسجين فى الاحماض الامينية.

فى الدهون لوحظت ازاحات رامان فى المنطقة 720, 1446, و 2800 سم⁻¹. وكانت الرابطة 2921 سم⁻¹ فى الدهون المشبعة قد ظهر فيها انزياح وترجع الى الاهتزاز غير المتماثل فى رابطة كربون-هيدروجين. وأيضاً سجلت إزاحات رامان في المنطقة 779سم⁻¹ وتمثل الرابطة مجموعة CH₂, والمناطق الطيفية 1120, 1499, و 1002 و 1310سم⁻¹ فى الاحماض النووية.

فى تحويلات فوريرير للاشعه تحت الحمراء وجدت فروقات طيفية بين عينات اللوكيميا م مقارنة بعينة الدم السليمة وكانت فى البروتين عند 1548 و 1650سم⁻¹, وفى الدهون عند 2091 و 3540سم⁻¹ و فى الاحماض النووية عند 1170 و 1303سم⁻¹

نتائج فحص العينات بجهاز تحويلات فوريرير للاشعة تحت الحمراء اظهرت زياده فى شدة الطيف لعينات سرطان الدم مقارنة بعينة الدم السليمة. ولوحظ ان هناك تفاوت فى الشده بين العينات المريضة مقارنة بالعينة السليمة و لم يكن هناك اختلاف فى موضع الطيف بالنسبة للعينات المريضة.

عند المقارنة بين التقانتين, نستخلص ان مطيافية رامان ذات قدرة عالية على تحليل طيف العينات ودقة اكبر فى تحديد مكونات المركب ومواقع الروابط المكونة للمركب من مطيافية تحويلات فوريرير للاشعة تحت الحمراء. كلا التقانتين أمكن استخدامها في تشخيص عينات سرطان الدم بكفاءة.
