

Dedication

I dedicate this work to my mother Haja Hawaa and my father Haj Ishag who had offered me their love, spared their unlimited effort to, and spent their valuable time to care for and educate me. In addition, I dedicate this work to my honest wife Khansa Ibrahim Suleiman, who has given me unlimited support to accomplish this work, and my sisters, my brothers and their families.

The same dedication is extended to my teachers, friends and for all the people who have stood by me and appreciate all needed they have given me, asking Allah to bless them.

Acknowledgements

First, I would like to express my feeling, emotions, and appreciation to Allah, for giving me the strength to complete this research.

I would like to thank my supervisor Dr. Huda Mohamed Kamal for her fruitful advice and guidance. She has spent a lot of effort to help me. Her encouragement, assistance and patience have inspired me to greater effort.

I would like to thank my co. supervisor Dr. Taj Elden Abd Elgawi Taj Elden (Bahri University) who helped me in collection of performing devices and the practical part of my work. My thanks are also due to all the members of physics department of my college especially Us. Mohamed Abd El hai Abd El Rahman.

In addition, I would like to thank the Sudan University of Sciences and Technology, which has carefully led me study.

Abstract

Three brick clay samples were prepared by mixing the garirh earth from Jazeera state and kaolin from North state with different percentages for three samples. The refractory bricks components, were for sample-1 (75% garirh, 25% kaolin), sample-2 (70% garirh, 30% kaolin), and sample-3 (80% garirh, 20% kaolin). The specific heat capacity of the three samples and the thermal conductivity were calculated. The three samples were analyzed using a Canberra 35+ device and the concentrations were obtained. The results of the thermal conductivities of the brick sample products were found to decrease from 0.0261 (W/m K) for the sample-1(75% garirh, 25% kaolin) to 0.01799(W/m K) for the sample-3 (i.e. ~32%), for the sample 80% garirh, 20% kaolin.

A device assembled by the researcher Mohamed Ishag measured the humidity ratio of the three samples. It is an electronic device consisting of a port connected to LCD water screen to display the reading of humidity inside and outside the room, and a microcontroller of 16L mega, which was programmed by the computer using the program Bas com AVR and the data was then transferred to the electronic port. Finally, two DHT11 sensors were used to measure the internal and external humidity. The reading were recorded every hour after performing measurements of the humidity of the three samples, a graph with the ratio of humidity versus the time of each sample was drawn from 6 am to 10 pm. The results of all three samples were obtained, all of which showed high humidity in the morning, and very low humidity at noon interval, then it rises and becomes very high at evening again.

The idea of a humidity Sensor was transferred to the humidity meter by an electronic circuit assembled by the researcher which consists of microcontrollers and the computer program as basic components.

The researcher concluded that in the hot area, the best sample of the refractory bricks samples was sample-3, which consists of (70 % garirh, 30 % kaolin). While in the humid areas, the best sample was sample 1. It is made up of (75% garirh and 25% kaolin).

المستخلص

أعدت ثلاثة عينات من طوب الطين بواسطة خلط تراب القريرة من ولاية الجزيرة والكاولين من ولاية الشمالية بنسب مختلفة للعينات الثلاثة، وهي مكونات الطوب الحراري. العينة الأولى تتكون من (75% قريرة و25% كاولين)، العينة الثانية (70% قريرة و30% كاولين) والعينة الثالثة (80% قريرة و20% كاولين). حللت العينات الثلاثة وتم الحصول على التركيز بواسطة جهاز الكاميرا 35+. ثم حسبت الحرارة النوعية والموصلية الحرارية للثلاثة عينات. وتم الحصول على نتائج الموصلية الحرارية لمنتجات عينات الطوب ووجد بانها تقل من 0.0261 وات لكل متر كلفن للعينة المكونة من (75% قريرة و25% كاولين) الي 0.01799 وات لكل متر كلفن للعينة المكونة من نسبة 80 في المئة من القريرة ونسبة 20 في المئة من الكاولين.

حسبت نسبة الرطوبة للعينات الثلاث بواسطة جهاز تم تجميعه من قبل الباحث محمد اسحق مصطفى وهو جهاز إلكتروني يتكون من منفذ إلكتروني متصل بشاشة مائية LCD وهي تستخدم لعرض قراءة الرطوبة داخل وخارج الغرفة، و متحكممة 16 ميكا والتي تم برمجتها بالكمبيوتر باستخدام برنامج باص كوم ومن ثم نقلت البيانات الي المنفذ، وأخيرا حساسين DHT11 لقياس الرطوبة الداخلية والخارجية. بعد تسجيل قراءات الرطوبة للعينات الثلاثة لكل ساعة، من الساعة 6:00 صباحا وحتى الساعة 10:00 مساء، رسم رسماً بيانياً لنسبة الرطوبة مقابل الزمن. وقد تم الحصول على نتائج العينات الثلاثة، وكلها ذات رطوبة عالية عند الصباح، ومنخفضة جدا عند فترة الظهر، ثم ترتفع وتصبح عالية جدا عند المساء.

تم تحويل فكرة جهاز حساس الرطوبة الي جهاز قياس الرطوبة بواسطة دائرة إلكترونية تم تجميعها بواسطة الباحث والتي تتكون من الميكروكنترولر وبرنامج الحاسوب كمكونات أساسية

يوصي الباحث في المناطق الحارة باستخدام العينة الثالثة، المكونة من (70% قريرة، 30% كاولين). أما في المناطق الرطبة، فالعينة الأفضل هي العينة الأولى المكونة من (75% قريرة و75% كاولين)
