**My lovely mother**

**My sisters, brothers and friends**

## **Acknowledgments**

I would like to express my special thanks to my dear supervisor,

**Dr. Allia Mohammed Osman**, for her brilliant ideas,  
endless support and guidance throughout this study.

I am grateful for her patience and continuous encouragements and generous  
supply of references and leading supervision

I would like to express my gratitude to my family.

Sincere thanks to my friends for their precious friendship and continuous  
support. Especially, the friends who look after me in bad times.

## Abstract

Bored concrete piles are mostly used in Sudan Khartoum area for tall building, bridges and other heavily structures where the soil under which is very weak.

The purpose of this study is to analyze and design bored piles under general conditions of load in Khartoum area, particularly at Soba bridge site, to study how pile transform these loads to the ground. how these loads are distributed in each pile within the group piles and design it.

Using manual empirical formulas and computer software Allpile 6.5 to analyze different pile diameters (1.2,1.4,1.6and 1.8m), different pile lengths (25.9,32.9, and 35.9) and different numbers of pile groups (1x4,2x4 and3x4) subjected to vary load combinations to study the effect of change in diameter, length and number of piles in groups on pile behavior.

The results of settlement, deflection, axial, lateral load and moment on each pile in group were obtained to compare the results from manual empirical formulas with numerical software Allpile 6.5 and with the actual results which the bridge was designed.

The study has shown that the results of numerical software Allpile 6.5 analysis, manual empirical formulas calculations analysis and actual results are almost the same for the vertical load results. However, about the results of moment and lateral load the actual results which show large different compared to the software Allpile 6.5 and manual empirical formulas calculations results which they are often close.

The results indicate that the decrease in length effects on increase the settlement about 14.14% and the increase of diameter effect on the decrease the settlement by 22.59%. but the change in length does not influences on deflection. Also Increase the number of piles in the group decrease the loads applied on each pile.

finally, the pile has been designed calculating the reinforcement for safety and durability. Comparison of this with the actual design shows that more pile length is required because the actual length is 25.9m for 1X4 group, the satisfied length for the design requirement in this research is 35.9m for 1X4 group.

## التجريد

الخوازيق الخرسانية المحفورة (bored concrete piles) أكثر استخداماً في السودان، منطقة الخرطوم، للمباني العالية والجسور والمنشآت الثقيلة التي تقام على ترابه ضعيفه .

الغرض من هذه الدراسة هو تحليل وتصميم الخوازيق الخرسانية المحفورة المطبق عليها القوي المختلفة في منطقة الخرطوم بالتحديد عند موقع كبري سوبا ودراسة كيفية نقل الخازوق للاحمال الي التربه وكيفية توزيع هذه الاحمال على كل خازوق داخل مجموعه الخوازيق وتصميمه .

بإستخدام المعادلات التجريبيه اليدويه وبرنامج حاسوبي Allpile6.5 لتحليل اقطار المختلفه للخازوق (1.2, 1.4, 1.6, 1.8 متر) والاطوال المختلفه للخازوق (25.9, 32.9 و 35.9 متر) وايضا وعدد مختلف من مجموعات الخوازيق (1x4, 3x4 و 2x4) معرضة لمجموعة من الأحمال المتغيرة لدراسة تأثير التغير في القطر والطول وعدد الخوازيق في المجموعه على سلوك الخازوق.

تم الحصول على نتائج الهبوط والانحراف والقوي المحورية والقوي العرضية لكل خازوق في المجموعة و ذلك لمقارنة نتائج المعادلات التجريبيه اليدويه بنتائج البرنامج الحاسوبي Allpile6.5 و ايضا بنتائج الفعلية للتصميم.

هذه الدراسة أظهرت أن النتائج من التحليل العددي باستخدام برنامج حاسوبي Allpile6.5 و النتائج باستخدام المعادلات التجريبية اليدوية والنتائج الفعلية للتصميم تقريباً متساوية بالنسبة للقوة الراسية . لكن بالنسبة لنتائج العزوم والقوي الافقية أظهرت النتائج الفعلية للتصميم فرق كبير عن نتائج التحليل باستخدام برنامج حاسوبي Allpile6.5 و المعادلات التجريبية اليدوية التي تكون في الغالب متقاربة.

أشارت النتائج الي أن تقليل الطول يؤثر في زياده الهبوط حوالي 14.14% وأيضا زيادة القطر تؤثر في الهبوط 22.59%, ولكن وجد ان تغيير الطول لا يؤثر في الانحراف . وايضا زيادة عدد الخوازيق في المجموعة يقلل من القوي المطبقة على الخازوق .

وأخيراً تم تصميم الخازوق تحت الاحمال وحساب التسليح المناسب للامان والديمومة. أظهرت المقارنه مع التصميم الفعلي توجد حوجه الي زياده طول الخازوق لأن الطول الفعلي هو 25.9 متر لمجموعة 1X4 , لكن طول الكافي لمتطلبات التصميم في هذا البحث هو 35.9 متر لمجموعة 1X4 .

## List of Symbols:

$(A_s)_i$	surface area of the pile in the layer.
$A'_s$	area of shaft that is effective in developing skin friction.
$A_p$	area of the pile tip.
$A_p$	area cross section of pile.
$A_s$	effective surface area of the pile in contact with the soil.
$B$	width of the pile.
$c$	cohesion of the soil at depth $z$ .
$d$	center to center pile spacing.
$D$	depth of the piles below ground level.
$D_s$	diameter of bored pile.
$E$	modulus of elasticity in the pile material.
$E_p$	modulus of elasticity of bored pile.
$E_p$	modulus of elasticity of the pile material.
$E_s$	modulus of elasticity of soil at or below the pile point.
$E_u$	deformation modulus for the undrained loading conditions.
$f_{(z)}$	variation of with depth.
$f_s$	average unit skin friction between the sand and the pile surface.
$f_s$	unit friction resistance at any depth.
$G_s$	shear modulus of soil.
$H$	thickness of the soil layer.
$H_i$	thickness of layer $i$
$I$	moment of inertia of the pile.
$I_p$	influence factor.

- $k$  coefficient of horizontal subgrade reaction.
- $K$  earth pressure coefficient.
- $K_0$  earth pressure coefficient at rest.
- $K_p$  Rankine's coefficient of passive pressure.
- $L$  length of pile.
- $n$  number of layers in which the pile is installed.
- $N$  number of piles in group
- $n_1, n_2$  number pile in group in each direction.
- $N_c$  bearing capacity factor.
- $N_c^*, N_\gamma^*, N_q^*$  bearing capacity factor .
- $N_{\sigma^*}$  bearing capacity factor.
- $P$  perimeter of the pile section.
- $p'$  pressure on soil.
- $p_{oz}$  effective overburden pressure at depth  $z$ .
- $p_{oz}$  the effective overburden pressure at a depth  $z$ .
- $P_z$  passive resistance at any depth.
- $Q_{all}$  allowable load-carrying capacity for each pile.
- $Q_g$  ultimate load for group piles.
- $q_n$  net foundation pressure.
- $q_p$  ultimate bearing capacity of the soil at the pile tip.
- $Q_p$  point (or base or tip) resistance of the pile.
- $Q_s$  shaft resistance develop by friction (or adhesion) between the soil and
- $Q_u$  ultimate load for single pile.
- $q_{wp}$  point load per unit area at the pile point.

- $Q_{wp}$  load carried at the pile point under working load condition.
- $Q_{ws}$  load carried by frictional (skin) resistance under working load
- $R_1$  ratio of moment of inertia of drilled shaft section to moment of inertia.
- $R$  Stiffness factor
- $\tan \delta'$  coefficient of friction between sand and the pile material.
- $T$  Stiffness factor
- $y$  Deflection of the pile.
- $\alpha'$  effective vertical pressure at the pile tip.
- $\gamma'$  effective unit weight of sand.
- $\delta'$  soil – pile friction angle =  $0.8\phi'$ .
- $\lambda$  friction capacity factor.
- $\mu_s$  Poisson's ratio of soil.
- $\sigma_z$  average effective vertical stress imposed on the soil layer due to the net foundation pressure  $q_n$  at the base of the equivalent raft foundation
- $\sigma'_0$  average effective overburden pressure.
- $\sigma_0$  mean effective normal ground stress at the level of pile point.
- $\bar{\sigma}_0$  mean effective vertical stress for the embedment length.
- $\bar{\sigma}_v$  effective vertical pressure at that depth thus unit skin friction.
- $\sigma'_{(0)i}$  effective normal stress in the layer.
- $\nu$  shear stress.
- $\nu_c$  ultimate shear stress in concrete.
- $\phi'$  effective soil friction angle.
- $\phi'$  effective friction angle of the bearing stratum.
- $\Delta$  average Volumetric strain in the plastic zone below the pile point
- $\Delta L$  increment pile length over which  $p$  and  $f$  are taken to be constant.

**Chapter One**  
**General Introduction**

# Chapter One

## General Introduction

### 1.1 Introduction:

The use of pile is oldest method of solving the soft soil problem to carry heavy load from tall building, bridges. piles are used to transmit the load to stronger layer, when this layer is in deeper depth.

When the load is too heavy to carry by single pile then the group of pile is necessary to carry the loads. Many researchers study pile and group of pile under loads to determine the capacity of piles to carry loads , most researcher depending their research on the field observations; in-situ full-scale and laboratory model tests were widely conducted on vertically and laterally loaded piles (including piers and drilled shaft etc.) to computing bearing capacity.

Central of Khartoum which the case study area are alluvium deposits, they grade with depth from clay near the ground surface in to silts and sand with gravel down to Nubian formation (Al-amery,2005). These formations are either exposed or covered by the recent quaternary formations. They cover large areas in Northern, Central Western and Eastern Sudan. Several important heavy structures such as bridges across the rivers and high-rise buildings in Khartoum are supported on these formations (Elsharief, 2014).

Shallow soil cannot carry heavy structure loads therefore, pile foundation is used.

### 1.2 Problem statement:

Analysis pile and pile group under general conditions how the pile carry the general conditions loads and transform it to the ground as single pile? also how the pile behave under these loads inside the group of pile? Most researchers analyze piles and group of piles and verify the results by compression with the experimental observations field. In this study the results of theoretical calculations will be compared with results of software program and actual results. That will help to verify the accuracy results.

### **1.3 Research objective**

The aim of the study is to analyze numerically and manually and design pile for different diameters and lengths

Objectives of the study are:

1. To learn how to analyze and design bored pile manually.
2. To analyze and design bored pile using computer software.
3. To verify the accuracy of results by comparison with actual soba bridge pile foundation analysis and design results.

### **1.4 Methodology:**

- Comprehensive literature review on bored piles analysis and design based on published papers, books.... etc.
- Formulating theoretical framework collecting necessary data studying the manual methods and selecting and studying the selected software package (Allpile6.5).
- Applications of the manual and software methods to analyze the case study problem and obtaining results.
- Analysis discussion and verification of results by comparison with known results.
- Conclusions presenting recommendations and writing up the dissertation.

### **1.5 Outlines of thesis:**

Chapter One Presents the introduction writing the problem statement, the objective, the methodology and outlines of thesis.

Chapter Two Contains the theoretical background and literature review.

Chapter Three Gives details of methods of calculating capacity of vertical single pile in sand or clay soil, methods of analysis of lateral single pile. Methods of analysis group pile by simple equation and software program (All pile 6.5).

Chapter Four Presents the case study and result of analysis by theoretical equations and software. For a single pile calculating bearing capacity, ultimate lateral load for several diameters and lengths. also, analyze pile group under the static vertical load,

lateral load, moment for different diameter, length and number of piles in group of pile.

Chapter Five Illustrates graphically the results for analysis and discussion the effect of change pile diameters and lengths on the vertical capacity and ultimate lateral load of the pile. the distribution load of each pile in a pile groups for manual calculations, All pile software, actual results.

Chapter Six Gives summary and conclusions of the current work and the recommendations.

**Chapter Two**

**Historical Background  
and Literature Review**

## Chapter Two

### Historical Background and Literature Review

#### 2.1 Introduction:

Piles are columnar elements in a foundation which have the function of transferring load from the superstructure through weak compressible strata or through water, onto stiffer or more compact and less compressible soils or onto rock. They may be required to carry uplift loads when used to support tall structures subjected to overturning forces from winds or waves. Piles used in marine structures are subjected to lateral loads from the impact of berthing ships and from waves. Combinations of vertical and horizontal loads are carried where piles are used to support retaining walls, bridge piers and abutments, and machinery foundations.” (TOMILSON ,2008).

#### 2.2 The following list identifies some of the conditions that require pile foundations (Vesic, 1977)

- When one or more upper soil layers are highly compressible and too weak to support the load transmitted by the superstructure, piles are used to transmit the load to underlying bedrock or a stronger soil layer, as shown in Figure 2.1a.
- When bedrock is not encountered at a reasonable depth below the ground surface, piles are used to transmit the structural load to the soil gradually. The resistance to the applied structural load is derived mainly from the frictional resistance developed at the soil–pile interface. (See Figure 2.1b.)
- When subjected to horizontal forces (see Figure 2.1c), pile foundations resist by bending, while still supporting the vertical load transmitted by the superstructure. This type of situation is generally encountered in the design and construction of earth-retaining structures and foundations of tall structures that are subjected to high wind or to earthquake forces.
- In many cases, expansive and collapsible soils may be present at the site of a proposed structure. These soils may extend to a great depth below the ground surface. Expansive soils swell and shrink as their moisture content increases and decreases, and the pressure of the swelling can be considerable. If shallow foundations are used in such circumstances, the structure may suffer considerable damage. However, pile foundations may be considered as an alternative when piles are

extended beyond the active zone, which is where swelling and shrinking occur. (See Figure 2.1d) Soils such as loess are collapsible in nature. When the moisture content of these soils increases, their structures may break down. A sudden decrease in the void ratio of soil induces large settlements of structures supported by shallow foundations. In such as, pile foundations may be used in which the piles are extended into stable soil layers beyond the zone where moisture will change.

- The foundations of some structures, such as transmission towers, offshore platforms, and basement mats below the water table, are subjected to uplifting forces. Piles are sometimes used for these foundations to resist the uplifting force. (See Figure 2.1e.)
- Bridge abutments and piers are usually constructed over pile foundations to avoid the loss of bearing capacity that a shallow foundation might suffer because of soil erosion at the ground surface. (See Figure 2.1f.)” (DAS,2007).

Figure (2.1) Condition that require the use of pile foundations (DAS,2007)

### 2.3 Type of piles:

Type of pile classified according to several way that will show below:

### 2.3.1 Classification based on mode of transfer of loads:

#### 2.3.1.1 End bearing piles:

These piles transfer their load on to a firm stratum located at a considerable depth below the base of the structure and they derive most of their carrying capacity from the penetration resistance of the soil at the toe of the pile (see figure (2.2)). In this case, the ultimate capacity of the piles depends entirely on the load-bearing capacity of the underlying material; thus, the piles are called point bearing piles.

#### 2.3.1.2 Friction piles:

Carrying capacity is derived mainly from the adhesion or friction of the soil in contact with the shaft of the pile (see figure 2.2). When no layer of rock or rocklike material is present at a reasonable depth at a site, point bearing piles become very long and uneconomical.

These piles are called friction piles, because most of their resistance is derived from skin friction.

#### 2.3.1.3 Combined piles:

These piles transfer loads by a combination of end bearing at the bottom of the pile and friction along the surface of the pile shaft. the ultimate load carried by the pile is equal to the sum of the load carried by the pile point, and the load carried by the skin friction.

Figure (2.2) transfer of loads in pile

### **2.3.2 Classification according to material used:**

There are four types of pile according to materials used: (Tomlinson ,2008).

#### **2.3.2.1 Timber piles:**

Timber piles are made from tree trunk after proper trimming. the timber used should be straight, sound and free defects. Steel shoes are provided to prevent damage at the top pile during driving. The length of pipe sleeve should be at least five times the diameter of the pile.

Timber pile below the water table have generally long life. However, above the water table these are attacked by insects.

#### **2.3.2.2 Concrete pile:**

concrete piles may be divided into two basic categories:

- (a) precast piles.
- (b) cast-in-situ piles.
- (c) Prestressed concrete

(a) Precast piles can be prepared by using ordinary reinforcement, and they can be square or octagonal in cross section. Reinforcement is provided to enable the pile to resist the bending moment developed during pickup and transportation, the vertical load, and the bending moment caused by a lateral load. The piles are cast to desired lengths and cured before being transported to the work sites.

(b) Cast-in-situ, or cast-in-place, piles are built by making a hole in the ground and then filling it with concrete. Various types of cast-in-place concrete piles are currently used in construction, and most of them have been patented by their manufacturers. These piles may be divided into two broad categories:

- (a-1) cased.
- (b-2) uncased.

Both types may have a pedestal at the bottom. Cased piles are made by driving a steel casing into the ground with the help of a mandrel placed inside the casing. When the pile reaches the proper depth, the mandrel is withdrawn, and the casing is filled with concrete.

Figures 2.3a, 2.3b, 2.3c, and 2.3d show some examples of cased piles without a pedestal. Figure 2.3e shows a cased pile with a pedestal. The pedestal is an expanded concrete bulb that is formed by dropping a hammer on fresh concrete. The uncased piles are made by first driving the casing to the desired depth and then filling it with fresh concrete. The casing is then gradually withdrawn. Figures 2.3f and 2.3g are two types of uncased pile, one with a pedestal and the other without.

(c) Prestressed concrete piles can also be prestressed using high-strength steel prestressing cables. The ultimate strength of these cables is about. During casting of the piles, the cables are pre tensioned to about, and concrete is poured around them. After curing, the cables are cut, producing a compressive force on the pile section.

Figure (2.3) Cast in place concrete piles (DAS,2007).

### 2.3.2.3 Steel piles:

Steel piles have the advantages of being robust, light to handle, capable of carrying high compressive loads when driven on to a hard stratum, and capable of being driven hard to a deep penetration to reach a bearing stratum or to develop a high skin- frictional resistance, although their cost per metre run is high compared with precast concrete piles. They can be designed as small displacement piles, which is advantageous in situations where ground heave and lateral displacement must be avoided. They can be readily cut down and extended where the level of the bearing stratum varies; also, the head of a pile which buckles during driving can be cut down and re-trimmed for further driving. They have a good resilience and high resistance to buckling and bending forces.

Types of steel piles include plain tubes, box-sections, H-sections, and tapered. (Tomlinson ,2008).

#### **2.3.2.4 Composite piles:**

Combination of different materials in the same of pile. As indicated earlier, part of a timber pile which is installed above ground water could be vulnerable to insect attack and decay. To avoid this, concrete or steel pile is used above the ground water level, whilst wood pile is installed under the ground water level (see figure 1.7).

#### **2.3.3 Classification based on method of installation:**

A simplified division into driven or bored piles is often employed.

##### **2.3.3.1 Driven piles:**

Driven piles are displacement piles. In the process of driving the pile into the ground, soil is moved radially as the pile shaft enters the ground.

##### **2.3.3.2 Driven and cast - in- situ piles:**

These piles are formed by driving a casing with a closed bottom end into the soil The casing is later filled with concrete. The casing may or may not withdraw. (ARORA,2004)

Figure (2.4) Stages in installing pile Driven and cast - in- situ pile (Tomilson ,2008) (a) Driving piling tube. (b) Placing concrete in piling tube. (c) Compacting concrete in shaft. (d) Completed pile (Tomlinson ,2008).

### 2.3.3.3 Bored piles:

Bored piles a void is formed by boring or excavation before piles is produced. Piles can be produced by casting concrete in the void (figure 2.6). Some soils such as stiff clays are particularly amenable to the formation of piles in this way, since the bore hole walls do not require temporary support except cloth to the ground surface. In unstable ground, such as gravel the ground requires temporary support from casing or bentonite slurry. Alternatively, the casing may be permanent, but driven into a hole which is bored as casing is advanced. A different technique, which is still essentially non-displacement, is to intrude, a grout or a concrete from an auger which is rotated into the granular soil, and hence produced a grouted column of soil. (Tomlinson,2008)

Figure (2.5) method of construction (a) drilling to full depth (b)placing rebar cage (c) placing concrete(d) completed bored.

#### 2.3.4 Classification based on displacement of soil:

Based on the volume of the soil displacement during installation, the piles can be classified into two categories: (Tomlinson ,2008).

##### 2.3.4.1 Displacement piles:

All driven piles are displacement piles as the soil is displaced laterally when the pile is installed. the installation may cause heaving of the surrounding ground. Precast concrete and closed – end pipe piles are high displacement piles. Steel H- piles are low displacement piles.

##### 2.3.4.2 Non- displacement piles:

Bored piles are non- displacement piles. As the soil is removed when the hole is bored, there is no displacement of the soil installation. The installation of these piles causes very little change in the stresses in the surrounding soil. (Tomlinson ,2008).

## 2.4 Previous studies:

### **(Basile ,2003)**

Reviews of available computer programs for pile group analysis Estimation of geotechnical parameters using some applications in both the linear and nonlinear, attention is focused on correlations between these parameter and commonly available in-situ test data , also compare the application of available numerical methods with practical problem involving real soil .Effect of soil non linearity on pile group response, as measured experimentally and as predicted by numerical analysis . the main advantage of non-liner group analysis system over linear is reduction of loads in large groups.

### **(Elsharief. 2007)**

Summarizes the outcome of a research program carried out in Sudan to provide guidelines for the design of bored concrete piles in expansive soils. Design parameters were developed. The parameters under consideration are the adhesion, bearing capacity and uplift factors. The results of the full-scale tests showed that the compressive axial capacity of piles installed in expansive soil were significantly reduced by wetting. This resulted in recommending higher factor of safety (minimum 4.0), showed that the adhesion factor was 0.45 for moisture content below the plastic limit and linearly increased with moisture above the plastic limit. The end bearing capacity factor was back calculated from instrumented full-scale load tests and a value of 9 was attained. Uplift factor was found to be 0.2 from model pile tests.

### **(Ivsic,2013)**

Analyzes the bearing capacity and settlement of bored piles, as the most frequently used type of piles in local practice. Empirical methods based on geotechnical soil parameters for capacity estimation, introduce some simplifications which lead to neglecting certain elements of a complex pile-soil interaction. On the other hand, the results of pile field testing methods are a direct summary consequence of the overall complex conditions on pile-soil contact, the comparison of empirical procedures and in-situ tests conducted to determine bearing capacity and settlement of bored piles in soft soils. as results obtained by calculation methods are generally much higher that the bearing capacity values obtained by in-situ testing.

**(Elsharief, 2014)**

Summarizes the geotechnical characteristics of five bridge sites in Khartoum and the approaches used by the designers for estimating the bearing capacity of the piles. The designs were compared with the results from pile load tests carried out in the bridge sites. The analysis has shown that the approaches used for estimating the pile capacities in the NF are very conservative and un-realistic , this evaluation has shown that alternative design approaches or improvement in the used ones are needed for the designers to come out with a technically viable and sound design for piles socketed in the NF. Alternative design approaches or improvements of the currently used designs are needed.

**(Poulos,2014)**

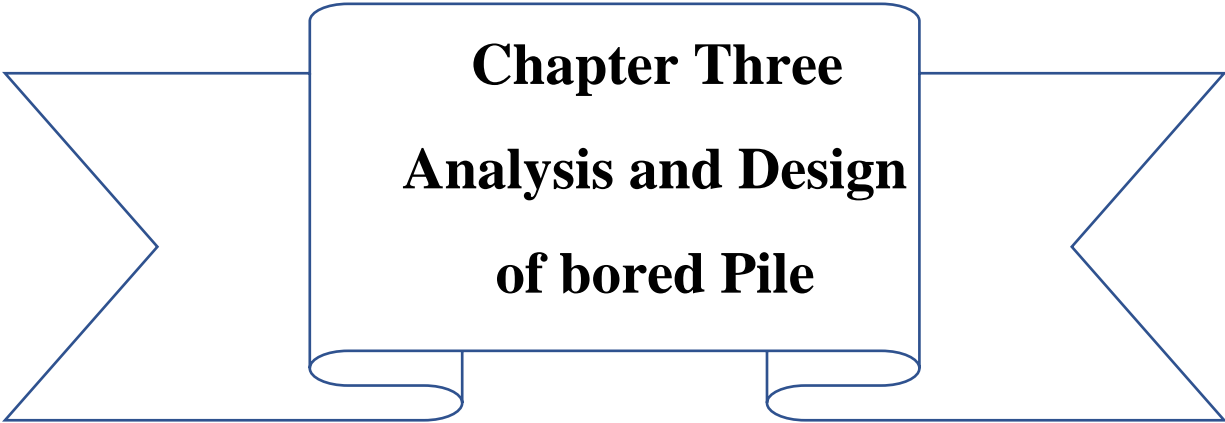

Presented for the analysis of general three-dimensional pile groups. The features of the pile-group model may include battered piles, different pile sizes, non-uniform pile sections, soil nonlinearity, soil inhomogeneity, and pile-soil-pile interaction. A typical six-pile group is analyzed and compared with results from three other computer programs for pile group analysis that are based on different approaches. This method is then used to analyze field and laboratory tests on groups of battered and vertical piles. The computed solutions are shown to be in good general agreement with the measured data. The present approach is shown to be at least as good as some of the computer programs currently available for pile-group analysis. Full-scale field tests and a lab and the results showed reasonably good agreement with the measured values.

**(Zhng ,2015)**

Present a simplified approach for nonlinear analysis of the load displacement response of a single and pile groups embedded in multilayered soils. The relationship between shaft displacement and skin friction was presented, a hyperbolic model was used to capture the relationship between skin friction and relationship between end resistance and end displacement pile-soil relative displacement developing along the pile-soil interface. The model of an individual pile in pile groups were proposed. Computer program was developed using the proposed models. comparison of load-settlement responses demonstrated that the proposed method is good agreement with the field observed behavior.

**(Priya,2017)**

Carry out parametric analysis of a group of piles by analyzing using finite element method (The STAAD Pro software) and comparing the results obtained using empirical equations (Brom's method and Vedic's method). The piles are modelled as linear elements. The effect of soil structure interaction is considered by assuming it as vertical and horizontal soil spring (Winkler soil spring). The pile group is subjected to both vertical and horizontal forces. Brom's methods which gave accurate results can be adopted for small scale projects and when software is not available for the analysis.

**Analysis and Design**  
**of bored Pile**

# Chapter Three

## Analysis and Design of bored Pile

### 3.1 Introduction:

In this chapter a general expression for the theoretical analysis using empirical formulas also, the software computer program Allpile 6.5. to analysis and design single, group pile under vertical, lateral load and moment is given and determine the piles settlement and deflection, while materials for piles can be precisely specified, and their fabrication and installation can be controlled to conform to strict specification and code of practice requirements.

### 3.2 Load transfer mechanism for piles:

The load transfer mechanism from a pile to the soil is complicated. To understand it, consider a pile of length  $L$ , as shown in Figure 3.1a. The load on the pile is gradually increased from zero to  $Q(z=0)$  at the ground surface. Part of this load will be resisted by the side friction developed along the shaft,  $Q_1$ , and part by the soil below the tip of the pile,  $Q_2$ . Now, how are  $Q_1$  and  $Q_2$  related to the total load? If measurements are made to obtain the load carried by the pile shaft,  $Q_z$  at any depth  $z$ , the nature of the variation found will be like that shown in curve 1 of Figure (3.1b). The frictional resistance per unit area at any depth  $z$  may be determined as

$$f(z) = \frac{\Delta Q(z)}{P(\Delta Z)} \quad (3.1)$$

If the load  $Q$  at the ground surface is gradually increased, maximum frictional resistance along the pile shaft will be fully mobilized when the relative displacement between the soil and the pile is about 5 to 10 mm, irrespective of the pile size and length  $L$ . However, the maximum point resistance will not be mobilized until the tip of the pile has moved about 10 to 25% of the pile width (or diameter). (The lower limit applies to driven piles and the upper limit to bored piles). At ultimate load (Figure 3.1d and curve 2 in (Figure 3.1b),  $Q(z=0) = Q_u$ . Thus,

$$Q_1 = Q_s \quad (3.2)$$

$$Q_2 = Q_p \quad (3.3)$$

At ultimate load, the failure surface in the soil at the pile tip (a bearing capacity failure caused by  $Q_p$  is like that shown in Figure 3.1e. Note that pile foundations are deep foundations and that the soil fails mostly in a punching mode, as illustrated previously in Figures 3.2e. That is, a triangular zone, I, is developed at the pile tip, which is pushed downward without producing any other visible slip surface. In dense sands and stiff clayey soils, a radial shear zone, II, may partially develop. Hence, the load displacement curves of piles will resemble those shown in Figure 3.2e. (Das,2007)

Figure (3.1) Load transfer mechanism for piles (Das ,2007)

### 3.3 Load carrying capacity of single piles:

Like shallow foundation, a pile foundation should be safe against shear failure and the settlement should be within the permissible limits. The methods for estimating the load carrying capacity of a pile foundation can be grouped into the following three categories:

### 3.3.1 Dynamic formula:

The ultimate capacity of pile driven in certain type of soil is related to the resistance against penetration developed during driving operation. pile to further penetration by driving depend upon the energy imparted to the pile by the hummer. it is tacitly assumed that the load carrying capacity of pile equal to the dynamic resistance during driving.

### 3.3.2 Pile load test:

load test may be carried out either on a driven pile or a cast-in-situ pile. Load tests may be made either on a single pile or a group of piles. Load tests on a pile group are very costly and may be undertaken only in very important projects.

Pile load tests on a single pile or a group of piles are conducted for the determination of:

- Vertical load bearing capacity.
- Settlement.
- Uplift load capacity,
- Lateral load capacity.

Generally, load tests are made to determine the bearing capacity and to establish the load settlement relationship under a compressive load. The other two types of tests may be carried out only when piles are required to resist large uplift or lateral forces.

### 3.3.3 Static methods:

the static methods give the ultimate capacity of an individual pile, depending upon the characteristics of the soil. The ultimate load

capacity is given by

$$Q_u = Q_p + Q_s \quad (3.4)$$

$$Q_p = q_p A_p \quad (3.5)$$

$$Q_s = q_s A_s \quad (3.6)$$

The ultimate bearing capacity ( $q_p$ ) of the soil at the pile tip can be computed from the bearing capacity equation similar to that for a shallow foundation, Terzaghi (1943) was the first to present a comprehensive theory for the evaluation of the ultimate bearing capacity of rough shallow foundations. (Arora, 2004)

According to Terzaghi's equations (Das,2007)

(for shallow square foundation)

$$q_u = 1.3c'qN_c + q'N_q + 0.4\gamma B N_\gamma \quad (3.7)$$

(for shallow circle foundation)

$$q_u = 1.3c'qN_c + q'N_q + 0.3\gamma B N_\gamma \quad (3.8)$$

Because the width to Depth for pile is relatively small, then  $\gamma D N_\gamma^*$  may be dropped from the equation without introducing error.

$$q_p = c'N_c^* + qN_q^* \quad (3.9)$$

The point bearing of the pile is

$$Q_p = q_p A_p = A_p (c'N_c^* + qN_q^*) \quad (3.10)$$

### 3.3.1.1 Meyerhof's method for estimating $Q_p$ :

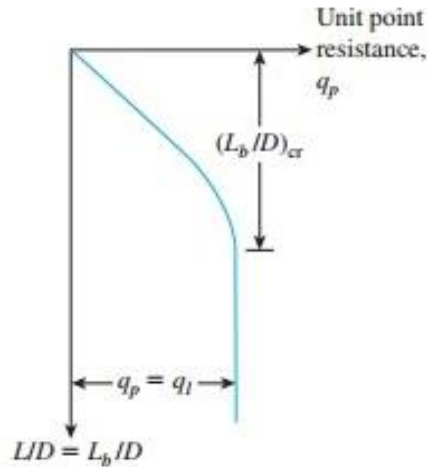

- **Sand ( $c=0$ ):**

The point bearing  $q_p$ , of a pile in sand generally increases with the depth of embedment in the bearing stratum and reaches a maximum value at an embedment ratio of

$$L_b/D = (L_b/D)_{cr} \quad (3.11)$$

$L_b$  is equal to the actual embedment length of the pile. Beyond the critical embedment ratio  $(L_b/D)_{cr}$ , the value of  $q_p$  remain constant ( $q_p = q_1$ ).

That is as shown in figure (3.2)

Figure(3.2) Nature of variation of unit point resistance in a homogeneous sand(Das,2007)

For piles in sand  $c = 0$  and equation 3.10 simplifies

$$Q_p = A_p q N_q^* \quad (3.12)$$

The bearing capacity factor  $N_q^*$  depend upon the angle of shearing resistance ( $\phi'$ ) is shown in (figure 3.3), however  $Q_p$  should not exceed the limiting value  $A_p q_1$ .

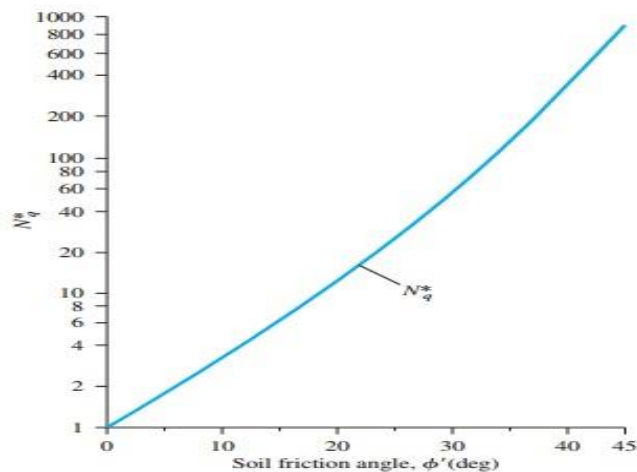

Figure (3.3) Variation of the maximum values of  $Nq^*$  with soil friction angle  $\phi'$  (Das,2007)

### 3.3.1.3 methods for estimating $Q_s$ :

- For Sand ( $c = 0$ )

The frictional or skin resistance  $Q_s$  of pile may be written as

$$Q_s = \sum p \Delta L f \quad (3.13)$$

the unit skin friction for a straight – sided pile depends upon the soil pressure acting normal to the pile surface and coefficient of friction between the soil and the pile material figure (3.5). (Arora, 2004)

Figure (3.4) Unit frictional resistance for piles in sand (Arora, 2004)

From figure (3.4) the soil pressure normal to the vertical pile surface is horizontal pressure ( $\sigma_h$ ) and is related to the effective vertical soil pressure as

$$\sigma_h = k \sigma_v \quad (3.14)$$

$$f_s = \sigma_h \tan \delta' \quad \text{or} \quad f_s = k \sigma_h' \tan \delta' \quad (3.15)$$

approximate value of K can obtain from the following equation. (Das,2007)

$$K = 1 - \sin \phi' \quad (3.16)$$

The value of K generally varies between 0.3 and 0.75. average value of 0.5 is usually adopted. K value is given in table (3.1) (Das,2007)

the value of  $\delta$  from various investigation appear to be in range from  $0.5\phi'$  to  $0.8\phi'$

Table (3.1) K value (Das,2007)

Type of pile	K
Bored or jettted	$K_0 \approx 1 - \sin \phi'$
Low – displacement driven	$K_0 \approx 1 - \sin \phi'$ to $1.4K_0 = 1.4(1 - \sin \phi')$
high– displacement driven	$K_0 \approx 1 - \sin \phi'$ to $1.8K_0 = 1.8(1 - \sin \phi')$

$$Q_s = f_s PL = (k \sigma_h \tan \delta') PL \quad (3.17)$$

As stated earlier, the effective vertical pressure ( $\sigma_v$ ) increases with depth only up to the critical depth below the critical depth, the value of  $\sigma_v$  remains constant.

The frictional resistance ( $Q_s$ ) can be expressed as (Arora, 2004)

$$Q_s = \sum_{i=1}^n K(\sigma_v)_i \tan \delta' (A_s)_i \quad (3.18)$$

The Equation (3.18) can be written as

$$Q_s = \sum_{i=1}^n K \tan \delta' (\text{area of } \sigma_v \text{ diagram}) * \text{pile perimeter} \quad (3.19)$$

The ultimate load for pile can be written for the sand soil as equation (3.4)

$$Q_u = q' N_p A_p + \sum_{i=1}^n K (\sigma_v)_i \tan \delta' (A_s)_i \quad (3.20)$$

### 3.4 Allowable load for pile:

After the total ultimate load-carrying capacity of a pile has been determined by summing the point bearing capacity and the frictional (or skin) resistance, a reasonable factor of safety should be used to obtain the total allowable load for each pile,

$$Q_{all} = \frac{Q_u}{F_s} \quad (3.21)$$

$F_s$  is factor of safety the factor of safety generally used ranges from 2.5 to 4, depending on the uncertainties surrounding the calculation of ultimate load. (Das,2007)

### 3.6 Analysis of pile to resist lateral loading:

Piles are frequently subjected to lateral load and for example quay and harbor structure where horizontal force are cause by the impact of ships during berthing and weave action , structure subject to wind load ,earth quake ,or pile supported earth-retaining structure .the problem of laterally loaded pile embedded in soil is closely related to the beam on an elastic foundation . A beam can be loaded at one or more

point along its length, where in the case of piles the external loads and moments are applied at or above the ground surface only.

A vertical pile resists a lateral load by mobilizing passive pressure in the soil surrounding it. (Das,2007)

The degree of distribution of the soil's reaction depends on

- (a) The stiffness of the pile,
- (b) The stiffness of the soil, and
- (c) The fixity of the ends of the pile.

### 3.6.1 Winkler's Hypothesis:

Most of the theoretical solution for laterally loaded pile involve the concept of subgrade reaction or otherwise termed as soil modulus which based on Winkler's assumption that a soil elastic medium may be approximated by a series of closely spaced independent elastic springs. (Murthy.1969)

based on this assumption

$$k = \frac{p' \text{ (KN /m)}}{y(m)} \quad (3.22)$$

using the theory of beam on elastic foundation we can write

$$EI \frac{d^4 x}{dz^4} = p' \quad (3.23)$$

Based on Winkler's model

$$p' = -k y \quad (3.24)$$

the sign negative because the soil reaction is in the direction opposite that of the pile deflection

combining the equations (3.64) and (3.65) gives for zero axial load:

$$EI \frac{d^4 x}{dz^4} + k y = 0 \quad (3.25)$$

### **3.6.2 Laterally loaded piles can be divided into two major categories:**

#### **3.6.2.1 Short or rigid piles:**

The lateral load required to cause failure of soil along the pile length (shear failure in the soil) before failure of the pile. (Das,2007).

the pile then rigid and its capacity governed by the soil resistance. (Poulos,1980)

A short rigid pile unrestrained at the top and having a length to width ratio of less than 10 to 12. The short rigid pile will fail by rotation when the passive resistance of the soil at the head and toe are exceeded figure (3.8a). rigid pile restrained at the head by a cap will fail by translation figure (3.8b). (Tomilson,2008)

#### **3.6.2.2 Long or elastic piles:**

The failure mechanism of an infinitely long pile is different. The passive resistance of the lower part of the pile is infinite, and thus rotation of the pile cannot occur, the lower part remaining vertical while the upper part deforms to a shape shown in Figure (3.5a). Failure takes place when the pile fractures at the point of maximum bending moment, and for the purpose of analysis a plastic hinge capable of transmitting shear is assumed to develop at the point of fracture. In the case of a long pile restrained at the head, high bending stresses develop at the point of restraint, e.g. just beneath the pile cap, and the pile may fracture at this point (Figure 3.5b). (Tomilson,2008)

The ultimate lateral resistance may be determined by the yield moment of pile which may be reached before full mobilization of the ultimate soil resistance. pile failure happened before the soil, lateral capacity of pile governed by pile characteristics, long piles would generally fail by bending. (Polous.1980)

Figure. (3.5) Long vertical pile under horizontal load  
 (a) Free head (b) Fixed head (Tomilson,2008)

### 3.6.3 Calculating the ultimate resistance to lateral loads :method to analysis single pile under lateral load:

#### 3.6.3.1 BrinchHasen's method

#### 3.6.3.2 Brom's method

The first step is to determine whether the pile will behave as a short rigid unit or as an infinitely long flexible member. This is done by calculating the stiffness factors R and T for the combination of pile and soil. The stiffness factors are governed by the stiffness (EI value) of the pile and the compressibility of the soil. The latter is expressed in terms of a 'soil modulus', which is not constant for any soil type but depends on the width of the pile B and the depth of the loaded area of soil being considered.

In the case of a stiff over-consolidated clay, the soil modulus is generally assumed to be constant with depth. (Tomilson,2008)

$$R = \sqrt[4]{\frac{EI}{kB}} \quad (3.26)$$

$$T = \sqrt[5]{\frac{EI}{n_h}} \quad (3.27)$$

Values of the coefficient of modulus variation  $n_h$  were obtained directly from lateral loading tests.

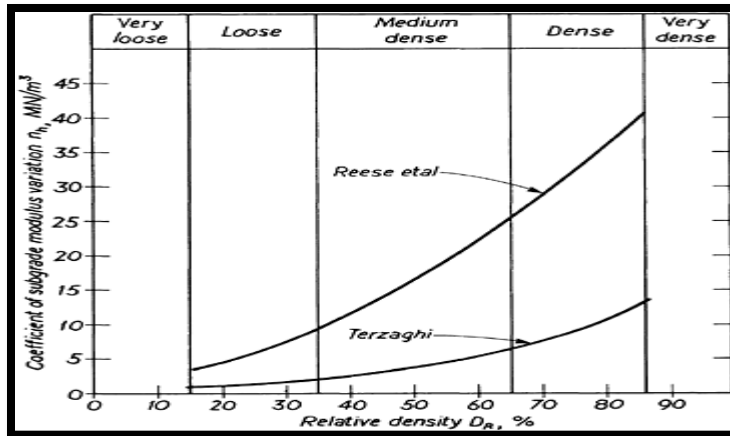

Figure (3.6) Relationship between coefficient of modulus variation and relative density of sands (Tomilson,2008)

Representative value of  $n_h$  Table (3.2) (Das,2007)

Soil	$n_h$	
	kN/m <sup>3</sup>	lb/in <sup>2</sup>
<b>Dry or moist sand</b>		
Loose	1800–2200	6.5–8.0
Medium	5500–7000	20–25
Dense	15,000–18,000	55–65
<b>Submerged sand</b>		
Loose	1000–1400	3.5–5.0
Medium	3500–4500	12–18
Dense	9000–12,000	32–45

Having calculated the stiffness factors R or T, the criteria for behavior as a short rigid pile or as a long elastic pile are related to the embedded length L as shows in table (3.3):

Table (3.3) Stiffness factor

Pile type	Soil modulus	
	Linearly-increasing	Constant
Rigid (free head)	$L \leq 2T$	$L \leq 2R$
Elastic (free head)	$L \geq 2T$	$L \geq 3.5R$

When  $L \geq 5T$  the pile considered to be long pile. for  $L \leq 2T$  the pile considered to be rigid. (Tomilson,2007)

### 3.6.3.1 Ultimate resistance of short rigid piles Brinchhansen's method:

Can be used to calculate the ultimate lateral resistance of short rigid piles. The method is a simple one which can be applied both to uniform and layered soils. The resistance of the rigid unit to rotation about point X in Figure (3.7) a is given by the sum of the moments of the soil resistance above and below this point.

Figure. (3.7) BrinchHansen's method for calculating ultimate lateral resistance of  
 c) Bending moment b) Shearing force diagram((short pile (a) Soil reactions  
 diagram (Tomilson,2008)

The passive resistance diagram is divided into a convenient number  $n$  of horizontal elements of depth  $L/n$ . The unit passive resistance of an element at a depth  $z$  below the ground surface is then given by

$$P_z = P_{Oz}K_q + CK_c \quad (3.28)$$

and  $K_{qz}$  and  $K_{cz}$  are the passive pressure coefficients for the frictional and cohesive components respectively at depth  $z$ .

BrinchHansen has established values of  $K_q$  and  $K_c$  in relation to the depth  $z$  and the width of the pile  $B$  in the direction of rotation, as shown in figure (3.8)

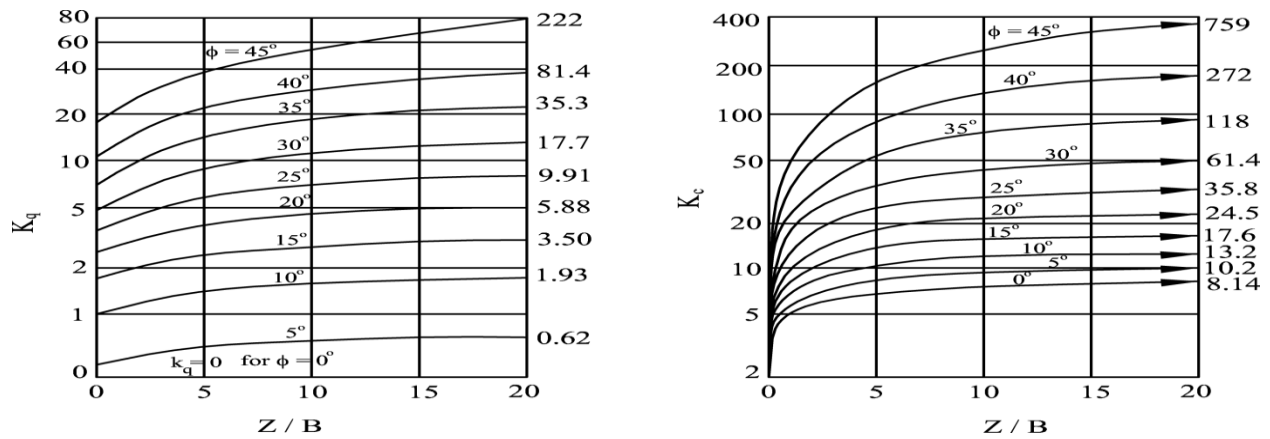

Figure (3.8) Brinch Hansen's coefficients  $K_q$  and  $K_c$  (Tomilson,2008)

The total passive resistance on each horizontal element is  $p_z(e + z)B$  and, by taking moments about the point of application of the horizontal load,

$$\sum M = \sum_{z=0}^{z=x} p_z \frac{L}{n} (e + z)B - \sum_{z=x}^{z=L} p_z \frac{L}{n} (e + z)B \quad (3.29)$$

The point of rotation at depth  $x$  is correctly chosen when the passive resistance of the soil above the point of rotation balances that below it. Point  $X$  is thus determined by a process of trial and adjustment. If the head of the pile carries a moment  $M$  instead of a horizontal force, the moment can be replaced by a horizontal force  $H$  at a distance  $e$  above the ground surface where  $M$  is equal to  $H \times e$ . Where the head of the pile is fixed against rotation, the equivalent height  $e_1$  above ground level of a force  $H$  acting on a pile with a free head is given by

$$e_1 = \frac{1}{2}(e + z_f) \quad (3.30)$$

where  $e$  is the height from the ground surface to the point of application of the load at the fixed head of the pile Figure (3.7), and  $z_f$  is the depth from the ground surface to the point of virtual fixity or the point of zero shear .

Having obtained the depth to the center of rotation from equation (3.29), the ultimate lateral resistance of the pile to the horizontal force  $H_u$  can be obtained by taking moments about the point of rotation, when

$$H_u(e + x) = \sum_0^x p_z \frac{L}{n} B(x - z)B + \sum_x^{x+L} p_z \frac{L}{n} + (z - x)B \quad (3.31)$$

The final steps in Brinchhansen's method are to construct the shearing force and bending moment diagrams Figure (3.7 b and 3.7 c). The ultimate bending moment, which occurs at the point of zero shear, should not exceed the ultimate moment of resistance  $M_u$  of the pile shaft. The appropriate load factors are applied to the horizontal design force to obtain the ultimate force  $H_u$ .

### 3.6.3.2 Brom's method :

Brom's (1965) developed a simplified solution based on the assumption of:

1. Shear failure in soil, which is case for short piles and
2. Bending of pile, governed by the plastic yield resistance of the pile section which applicable to long pile. (Das, 2007).

Brom's provide solution for both short and long piles installed in cohesive and cohesionless soil. He considered pile fixed or free to rotate at the head. (Murthy,1969).

- **Ultimate resistance of long piles:**

The passive resistance provided by the soil to the yielding of an infinitely long pile is infinite. Thus, the ultimate lateral load which can be carried by the pile is determined solely from the ultimate moment of resistance  $M_u$  of the pile shaft.

simple method:

$$\text{ultimate lateral load free headed pile } H_u = M_u / (e + z_f) \quad (3.32)$$

$$\text{ultimate lateral load fixed headed pile } H_u = 2M_u / (e + z_f) \quad (3.33)$$

$z_f$  should be taken as 1.4R for stiff, over-consolidated clay and 1.8T for normally consolidated clay, granular soils and silt. (Tomilson,2008)

- \* **Cohesion less soil:  $c = 0$**

For long piles in cohesion less soils the soil reactions and bending moments for free-headed piles are shown in Figure (3.29 a). The maximum bending moment on the pile shaft occurs at the point where the shearing force is zero.

Figure (3.9) Soil reactions and bending moments for long pile under horizontal load in cohesionless soil (Brom`s method) (a) Free head (b) Fixed head (Tomilson,2008)

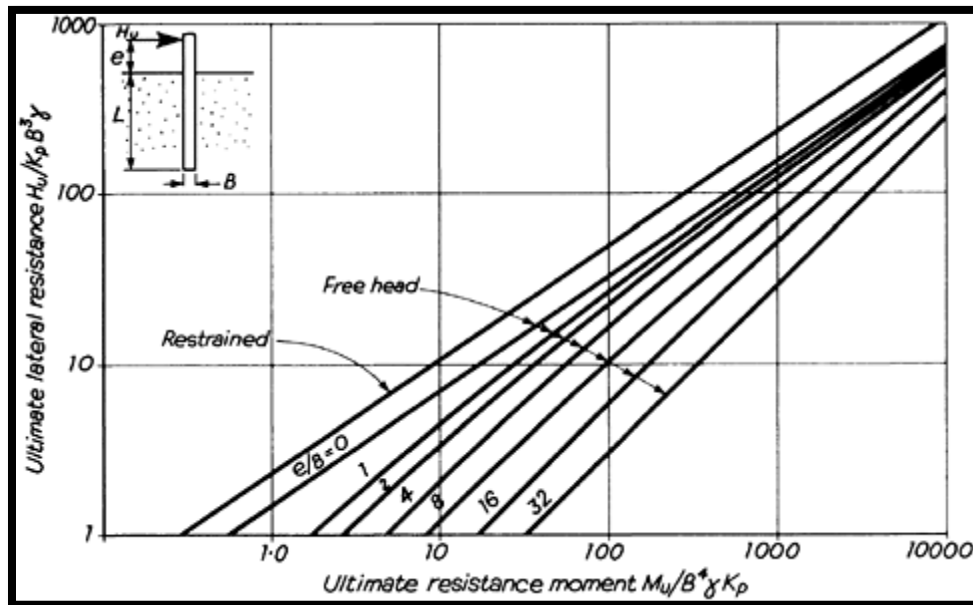

Figure (3.10) Ultimate lateral resistance of long pile in cohesionless soil related to ultimate resistance moment (Brom`s method) (Tomilson,2008).

Brom`s has established the graphical relationship between  $H/K_p \gamma B^3$

and  $M_u / (\gamma K p B^4)$  shown in Figure (3.21). These graphs can be used to determine the ultimate lateral load  $H_u$ .

### 3.7 Pile Group:

#### 3.7.1 Group action of piles:

In most cases pile group is used in to transmit the structural load that supported by several piles acting as a group to the soil. a pile cap is constructed over the group (pile) The load acts on the pile cap which distributes the load to the pile see figure (3.11).

Figure (3.11) Pile cap (Arora,2004)

The load carrying capacity of a pile group is not necessarily equal to the sum of the capacity of the individual piles. Estimation of the load carrying capacity of a pile group is a complicated problem. When the piles are spaced enough distance apart, the group capacity may approach the sum of the individual capacities. if the piles are closely spaced, the stresses transmitted by the piles to the soil may overlap, and this may reduce the load carrying capacity of the piles figure (3.12) and figure (3.13) .

Figure (3.12) Typical pile-group patterns: (a) for isolated pile caps; (b) for foundation walls (Bowls,1997)

Figure (3.13) soil overlap (Das.2007)

**3.7.2 The efficiency ( $\eta_g$ ) of a group piles:** are defined as the ratio of the ultimate load of the group to the sum of individual ultimate loads. (Das ,2007)

$$\text{Thus } \eta_g = \frac{Q_g(u)}{N Q_u} \times 100 \quad (3.34)$$

$$\eta_g = \frac{2(n_1 + n_2 - 2)d + 4d}{p n_1 n_2} \quad (3.35)$$

if  $\eta_g \geq 1$  in that case the piles will behave as individual piles

$$Q_g (u) = \sum Q_u \quad (3.36)$$

if  $\eta_g < 1$  then in this case

$$Q_g (u) = \eta_g \sum Q_u \quad (3.37)$$

### 3.8 General analysis of pile group:

In general, a pile group may be subjected to simultaneous axial load, lateral load, moment and possibly, torsional. Method of analyzing the pile group shown below:

#### 3.8.1 Simple statically method:

That ignore the presence of the soil and consider the pile group as purely structural system. Traditional design method has relied on consideration of the pile group as simple statically – determinate system, ignoring the effect of the soil. one such method which may be employed either graphically or analytically. Considering, for simplicity, load and pile having a pinned head, the steps in this method are as follows:

- assuming each pile to take an equal share of the vertical load on the cap and assuming the vertical load in pile caused by moment in the cap, to be proportional to the distance x, the vertical pile loads are calculated as

$$V_i = \frac{V}{N} + \frac{Mx_i}{\sum_{i=0}^n I_y} x + \frac{My_i}{\sum_{i=0}^n I_x} y \quad (3.38)$$

- There then a residual horizontal force H which is assumed to be equally distributed between each pile in the group.

It should be noted that this method cannot take in to account different conditions of fixity at the pile head and always assume zero moment at the head of each pile group is thus obtained. (Polous,1980)

- Pile group resist horizontal load by bending:

A group of vertical piles subjected to horizontal load H applied at the top of the pile is showing in figure (3.14). the piles are assumed to be fixed at the top and bottom.

Shear per pile. (Macginley,2009)

$$\text{Lateral load in each pile} = H/N \quad (3.39)$$

$$\text{Moment in each pile} = H h_1/(2N) \quad (3.40)$$

Where  $N$  is the number of pile and  $h_1$  is length of pile between fixed end.

Figure (3.14) (a) pile group (b) deflection (c) moment diagram

(Mcginley,2009)

### 3.9 Allpile6.5 software analysis:

The program Allpile6.5 from CivilTech software analyze pile load capacity efficiently and accurately. Allpile6.5 handle all type of pile, the program can perform the following calculation:

- Vertical capacity and deflection.
- Vertical capacity and settlement.
- Group vertical and lateral analysis.
- Static and cyclic condition.
- Negative and zero friction.

In this research negative and zero friction, cyclic condition not considering

Figure (3.15) group pile for vertical analysis

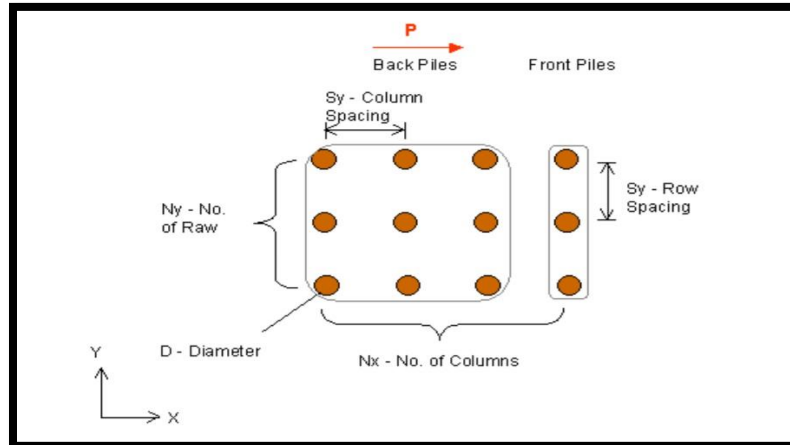

Figure (3.16) group pile for lateral load

### 3.9.1 Lateral load analysis:

The method utilized in the laterally loaded pile program, is based on the theory of subgrade reaction discussed above see equations (3.22 and 3.4).

#### 3.9.1.2 p-y concept of lateral load transfer:

when the basic beam – column is inserted vertically as pile shaft , the method of analysis Allpile6.5 consider the soil surrounding the shaft as a set of nonlinear elastic spring a depicted in figure (3.17) .this assumption is attributed to Winkler (1967) , and it states that each spring act independently , the behavior of one spring has no effect on any of the adjacent spring .

Figure (3.17) model of pile system with soil represented as set of nonlinear elastic spring (Reese, 1984).

in the analysis the response of spring can take as either linear or nonlinear. the approach in program Allpile6.5 is to treat the springs as nonlinear with their response represented by curves which relate soil resistance  $p$  to pile deflection  $y$ . in general , these curves are nonlinear and depend on several parameters including depth , pile geometry , shear strength of soil , and type of loading (static or cyclic).

A typical  $p$ - $y$  curve is shown in figure (3.18).

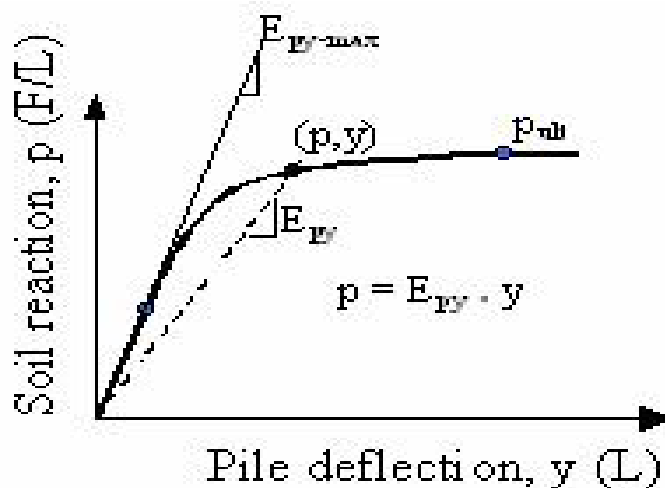

Figure (3.18) characteristic shape of  $p$ - $y$  curve (Reese, 1984)

The soil modulus  $E_s$  is defined as  $-p/y$  and is taken as the secant modulus to a point on p-y curve as shown in figure (3.18). Because the curve is strongly nonlinear, the soil modulus changes from initial stiffness  $E_{s1}$  to ultimate stiffness  $p_u/y_u$ . as can be seen the soil modulus  $E_s$  is not a constant except for small range deflection.

All pile directly program solve the nonlinear different equations representing the behavior of the pile – soil system to lateral (shear and moment) loading conditions in finite difference formulation using Reese's p-y method of analysis. For each set of applied boundary loads the program performs an iterative solution which satisfies static equilibrium and achieves an acceptable compatibility between force and deflection (p and y) in every element. The program uses the four nonlinear differential equation to perform the lateral analysis, equation (3.25).

### 3.9.2 The Allpile6.5 software input steps:

Allpile6.5 can be divided into six input pages:

First Pile type page: you can select the pile type there are twelve different type to choose.

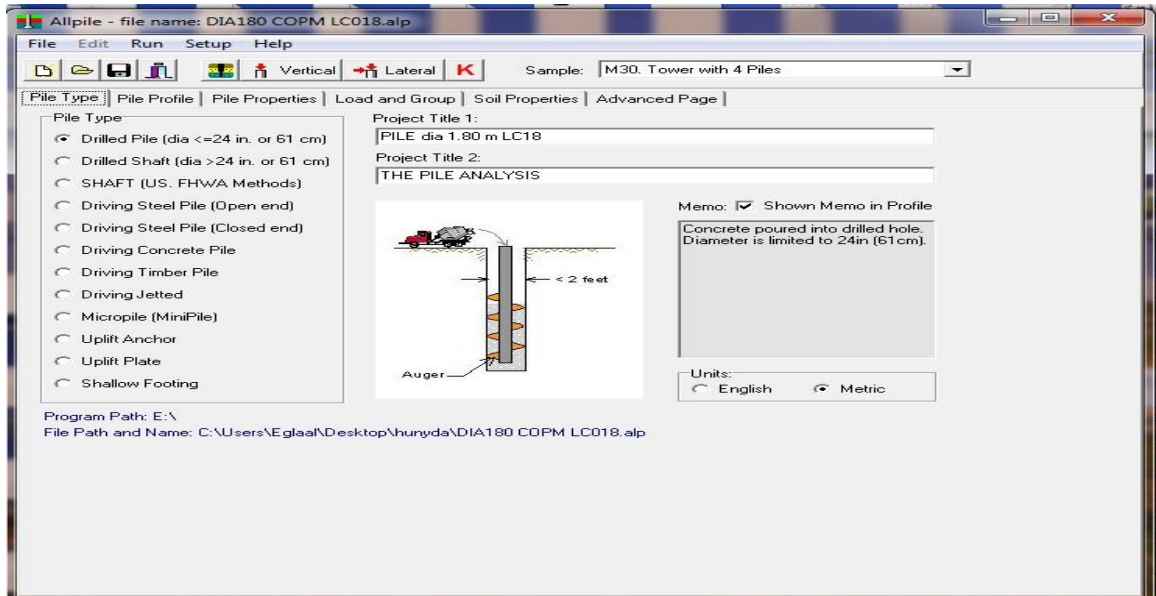

Figure (3.19) Pile type page

Second input pile profile page: input the pile length, distance from the ground level, surface angle and batter angle.

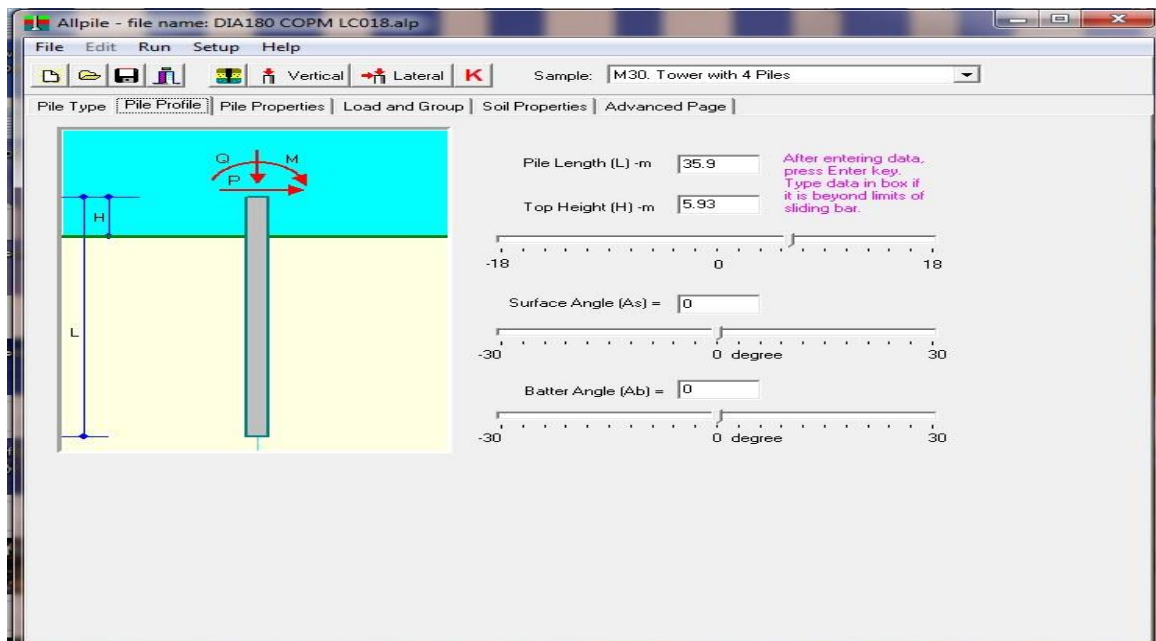

Figure (3.20) pile profile page

Third input pile property page: in this page input the data through the section is (width, area, perimeter, moment of inertia, elastic modulus, depth of pile,..... )

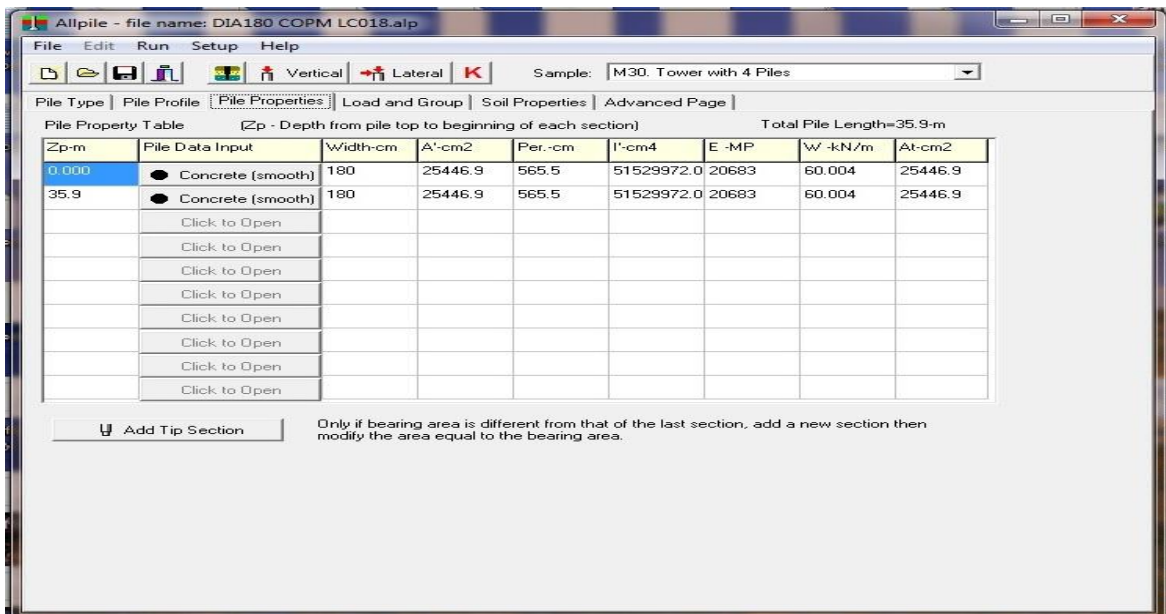

Figure (3.21) pile property page

Fourth input load and group: select the pile configuration that most fit to analysis (single pile, group pile or tower foundation), determine static or cyclic load and input vertical load, shear force (lateral load) , moment , torsion .

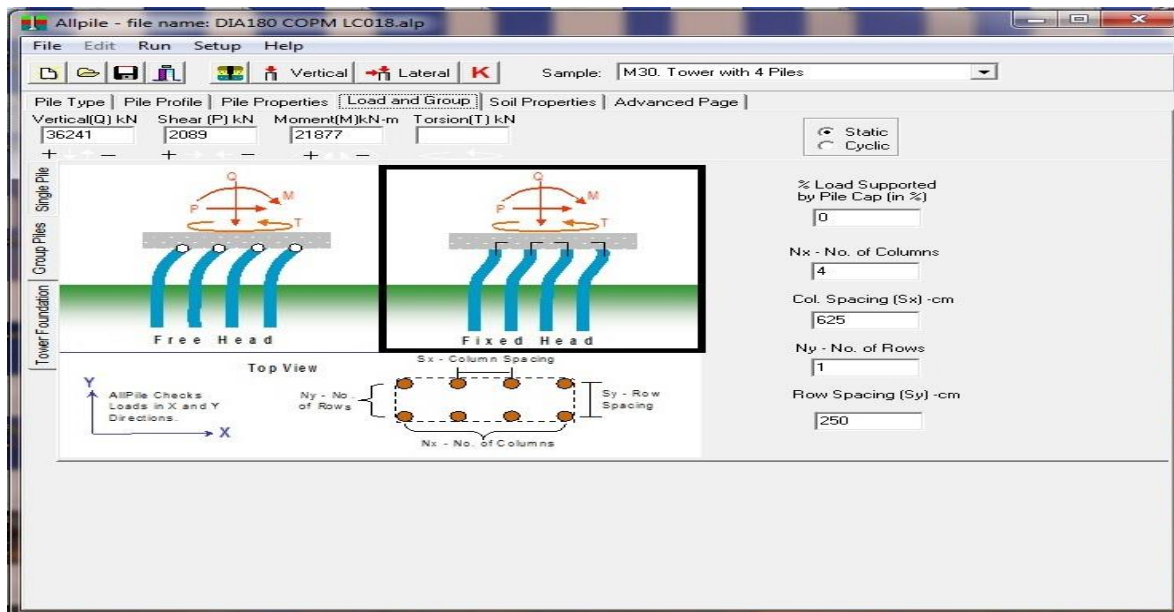

Figure (3.22) load and group page

Fifth input soil property page: input the parameters of the soil (angle of friction,) and must determine the water level.

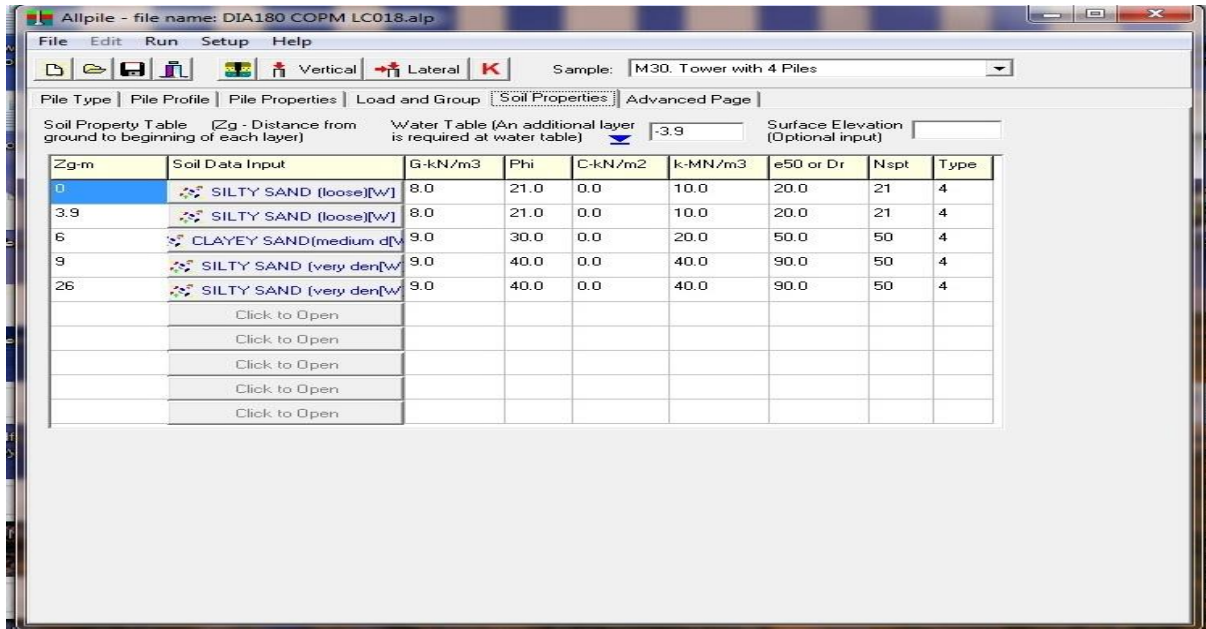

Figure (3.23) soil property page

Sixth advance page: this page allows to assign analysis parameter like factor of safety for vertical and lateral loads, resistance limit, allowable deflection.

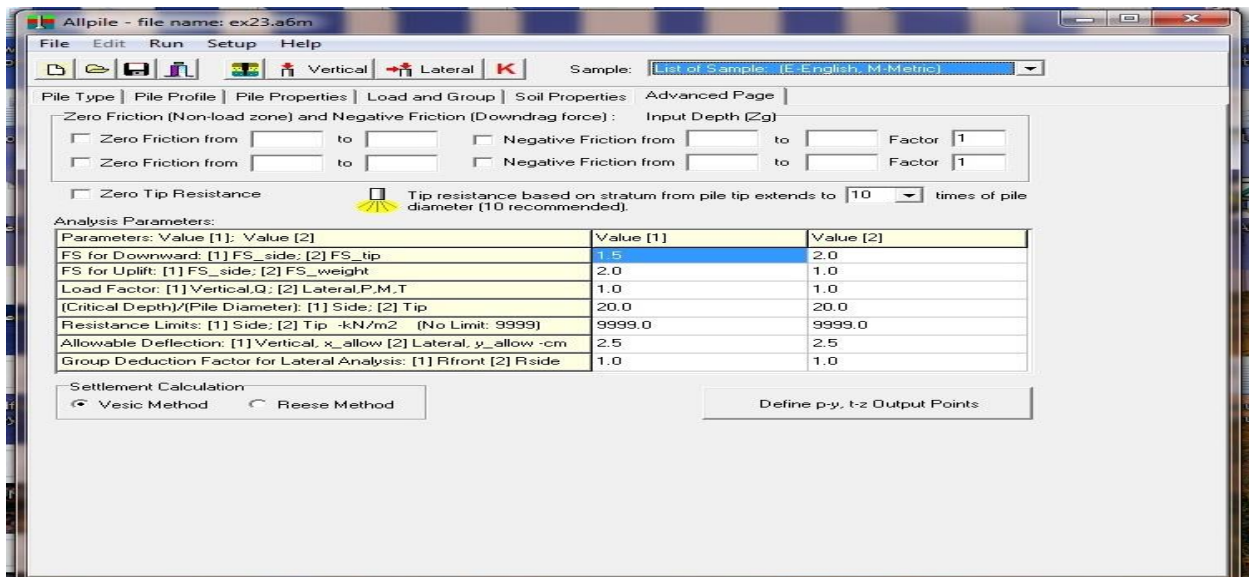

Figure (3.24) advance page

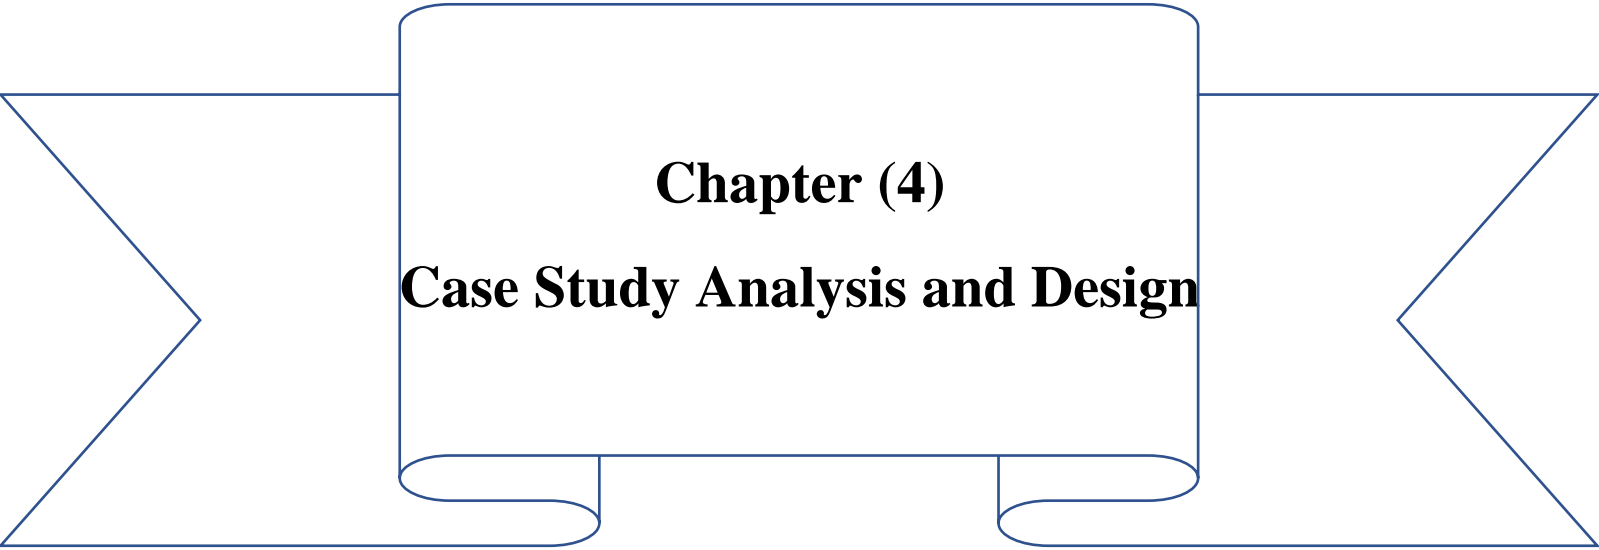

**3.9.3 This program provides the result as follows:**

Vertical analysis results: click on (vertical analysis) will display a panel that allows to choose the different type of result from analysis. for this analysis all lateral load components are ignored and only vertical load considering.

Lateral analysis results: click on (lateral analysis) will display a panel that provides several choices.

**3.10 Design of bored pile:**

in this research will design reinforce concrete pile under axial load moment and lateral load. when subjected to axial load and moment the reinforced concrete piles are considered as columns the effective lengths for various conditions of end restraint are given in BS 8110 respectively. (Tomilson,2008). But for lateral load will design as beam (Winkler's assumption).

**Chapter (4)**  
**Case Study Analysis and Design**

## Chapter Four

### Analysis Results and Design of Soba Bridge Piles

#### 4.1 Introduction:

In this chapter pile foundation of soba bridge have been studied. soba bridge contains 13 piers. piers from 1 to 3 in west shore, from 11 to 13 in east shore and from 4 to 10 which in river have been studied in this research.

In this study several diameters (1.20,1.6,1.40,1.80 m), several lengths (25.9,32.9 ,35.9m) and several pile groups (1x4,2x4,3x4) subjected to load combinations have been analyzed using manual empirical formula and software Allpile6.5.

**Soba Bridge:** this bridge located on the Blue Nile which connect east soba area with west soba area in Khartoum see figure (4.1) the bridge length is 571m and width is 6 ways. Published soil investigation recommendations for bored pile is 1.2m diameter and 30 m length but the actual analysis using 1.8 m for diameter and 25.9m for length and 1x4 for number of piles in group.

Figure (4.1) soba bridge location

### 4.2 Properties of soil for soba bridge:

Soba bridge soil properties shown in table (4.1) which is inside the river.

Table (4.1) Properties of soil for soba bridge

Description	Depth	Properties	Value
Silty sand (loose)	6m	$c'$	0
		$\phi'$	21 deg
		$\gamma'$	8 KN/m <sup>3</sup>
		K	1000 KN/m <sup>3</sup>
		K <sub>0</sub>	0.5
Clayey sand (medium dense)	3m	$c'$	0
		$\phi'$	30 deg
		$\gamma'$	9 KN/m <sup>3</sup>
		K	2000 KN/m <sup>3</sup>
		K <sub>0</sub>	0.45
Silty sand (very dense)	17m and more	$c'$	0
		$\phi'$	40deg
		$\gamma'$	9 KN/m <sup>3</sup>
		K	4000 KN/m <sup>3</sup>
		K <sub>0</sub>	0.35

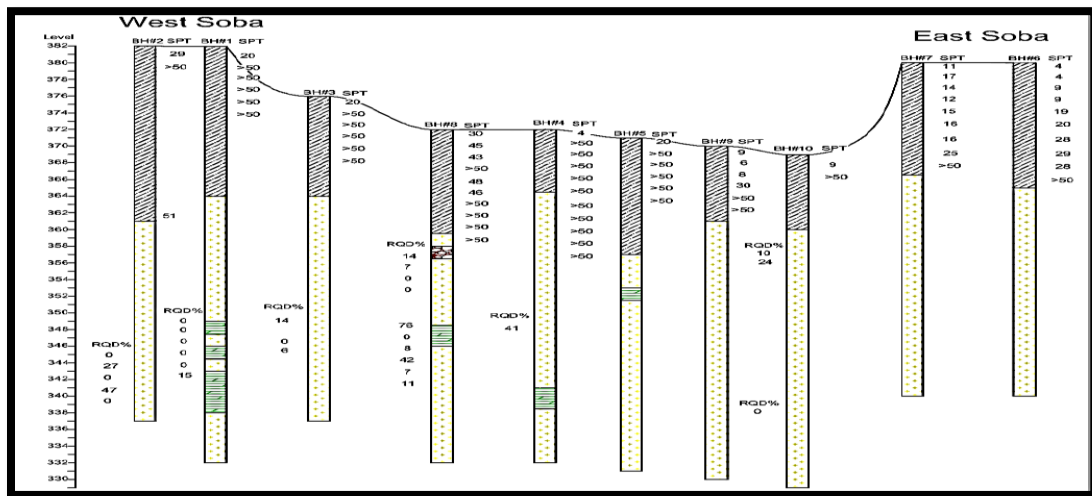

Figure (4.2) Subsurface profile of soba bridge site (Elsharief,2014)

### 4.3 Bearing capacity of vertical pile with several diameter and length:

To analysis and design pile it necessary calculates Bearing Capacity of pile to

know how much that pile can carry load without failure. Bearing capacity calculations by manual methods and with All pile soft were show below.

#### **4.3.1Pile bearing capacity manual calculation:**

use equations 3.12, 3.17 and 3.20 from previous chapter to calculate the ultimate capacity of an individual pile. to calculate the allowable load for pile, use the equation 3.21and compare the result with soil report and All pile 6.5 result.

Tables from (4.2) to (4.4) describe the pile bearing capacity results from soil report, manual calculations and All pile 6.5 software analysis for Lengths 39.5m ,32.9m and 25.9m respectively. (F.S is factor of safety).

Table (4.2) Bearing capacity of vertical pile length 35.9

#	Diameter m	Manual result		All pile result	Soil report result

Figure (4.3) Piers bridge

#### 4.4.1 Pile group vertical analysis:

Calculating group efficiency for all diameters using equation (3.34) to determine how the pile group behave according to  $\eta_g$  the results from table (4.6) represent that all pile behave as individual pile in group pile.

Table (4.6)  $\eta_g$  values

Diameter	$\eta_g$ group 1x4	$\eta_g$ for group 2x4
1.8	1.9	1.27
1.6	2.18	1.40
1.4	2.44	1.58
1.2	2.81	1.8

The spacing between piles in the groups 6.25 that is distance of piers which supporting the bridge deck that for 1x4 group for another group the spacing shown in figure (4.4). The spacing is more than 3D. using equation (3.38) to distribute the vertical load in each pile in the group.

**4.4.2 Pile group lateral analysis:** using equation (3.27) to determine the stiffness factor, according to table (4.7) find the lengths for all diameters greater than 5T then the pile describe as long pile.

Table (4.7) stiffness factor T for all diameters

Diameter m	$T$	5T
1.8	4.63	23
1.6	4.19	20.95
1.4	3.78	18.9
1.2	3.34	16.7

the equation from (3.39) distribute the lateral load, because pile is long using equation (3.33) to distribute the and moment in each pile in the group manually see tables from (4.10 to 4.64).

The limiting settlement criteria sometimes specified the net settlement should not be more than 25mm (Arrora,2004), The settlement should not be more than 25mm (Bowls, 1997). limits the lateral deflection at ground level to 25mm (Das,2007).

## 4.5 Calculate maximum moment and ultimate lateral load on pile.

### 4.5.1 Brom`s method:

Using the equation (4.1) and (4.2) to determine the yield moment for each diameter which is shown in table (4.7).

Table (4.8) shown ultimate lateral load which to calculated from equation (4.4) .

$$M_y = f_y * Z \quad (4.1) \text{ (Murthy, 1969)}$$

$$= f_y * \pi D^3 / 32 \quad (4.2)$$

For concrete assume the yield strength =  $f_y = f_{cu} = 30 \text{ N/mm}^2$

$$M_y = 30(\pi D^3 / 32) \text{ KN.m} \quad (4.3)$$

Table (4.8) maximum moment in pile Brom`s method

Diameter m	$M_y$
1.8	17176.6
1.6	12063.7
1.4	8081.74
1.2	5089.38

Ultimate horizontal load from figure (3.10), table (4.9) shows ultimate lateral load values of for different diameters.

Table (4.9) ultimate lateral load in pile Brom's method

Diameter (m)	$H_u$ (KN)
1.8	11022.48
1.6	7962.6
1.4	5927.04
1.2	1555.2

#### 4.5.2 Brinchhansen's method using spread sheet:

Calculating ultimate lateral load from spread sheet using brinchhansen method the figures from (A15) to (A18) shown values of ultimate lateral load for different diameters and lengths the table (4.10) represent the ultimate lateral load in pile using brinchhansen method.

Table (4.10) ultimate lateral load and maximum moment brinchhansen method in pile

Diameter (m)	$H_u$ (KN)
1.8	9711.5
1.6	9039.5
1.4	8356.3
1.2	7664.9

#### 4.6 The results:

The results of analysis the pile group of pile under four maximum load combinations (LC01, LC05, LC11, LC18), for diameter (1.2, 1.4, 1.6 and 1.8 m) and three different length (25.9, 32.9 and 35.9 m) by manual calculation ,Allpile6.5 software analysis and results report from A&A .

tables from (4.11 to 4.18) for L = 39.9m for 1x4 group pile results.

tables from (4.19 to 4.26) for L = 39.9m for 2x4 group pile results

tables from (4.27 to 4.34) for L = 32.9m for 1x4 group pile results.

tables from (4.35 to 4.42) for L = 32.9m for 2x4 group pile results.

tables from (4.43 to 4.50) for L = 25.9m for 1x4 group pile results.

tables from (4.51 to 4.54) for  $L = 25.9\text{m}$  for 1x4 group pile results (report from A&A).

tables from (4.55 to 4.62) for  $l = 29.9\text{m}$  for 2x4 group pile results

tables from (4.63 to 4.70) for  $l = 29.9\text{m}$  for 3x4 group pile results

1x4 pile group

2x4 pile group

3x4 pile group

### 4.7 Design of bored pile:

For design the pile using BS8110 code for LC18 load combination using chart for circular column in figure (4.5) and calculations in Table (4.71) to determine the area of steel and shear check.

The pile group designed 1x4 length 35.9 and diameter 1.8 to support all the load and the pile settlement and deflection in the design range.

Table (4.71) Calculation design for diameter 1.8 in 1x4 pile group.

4.71 design calculations:		
Diameter of main reinforcement( $\Phi$ )=30mm		
Diameter of link reinforcement=16mm		
Cover=70mm		
Compressive strength of concrete=30N/mm <sup>2</sup>		
Yield strength of reinforcement =460 N/mm <sup>2</sup>		
Maximum size of aggregate=20mm		
Exposure condition=Mild

### Analysis and Discussion of Results

#### 5.1 Introduction:

In this chapter have been studied effects in change of length and diameter on the axial capacity and ultimate lateral load of single pile, also study the variability of pile (diameter , length , number) in groups effect on pile deformation (settlement , deflection ) and loading distribution (vertical, lateral load , moment ) using the result from manual calculation and All pile 6.5 software analysis compare with the actual results that had calculated (using PileGroup software) for case study soba bridge project.

#### 5.2 vertical analysis results:

##### 5.1.1 maximum settlement for 1x4 group of pile results:

Figure from (5.1) to (5.4) represent the effect of increase the pile diameter in maximum settlement for length 35.9 m for group 1x4, the comparison shows that the maximum settlement decreases about 26.43% with increase the pile diameters (1.2, 1.4,1.6, 1.8m). The increase of pile diameter effects in the increase end bearing capacity which decrease the settlement.

Table (5.1)

Diameter	Maximum settlement
1.2	3.6547
1.4	2.17314
1.6	1.73842
1.8	1.41779

Figure (5.1) L=35.9 LC01 1X4 group pile maximum settlement represent table (5.1) which from table (4.11)

Table (5.2)

Figure (5.4) L=35.9 LC18 1X4 group pile maximum settlement represent table (5.4) which from table (4.17)

Figure from (5.5) to (5.8) represent the effect of increase the pile diameter in maximum settlement for length 35.9, 32.9 and 25.9 m for group 1x4, the comparison show that the maximum settlement decrease 26.43% ,24.49% and 22.59% respectively with increasing of diameters of pile for all load combinations (LC01,LC05,LC11,LC18).

Decrease of the length effect on maximum settlement. decrease length of pile from 35.9 m to 32.5 m increasing maximum settlement about 14.14%, decrease the length from 35.9 m to 25.9 m increasing maximum settlement about 39.79%, also decrease from 32.9 m to 25.9 m increase the maximum settlement. The decrease of pile length effects in the decrease skin resistance which increase the settlement.

Table (5.5)

<i>DIA</i>	Maximum Settlement L=35.9	Maximum Settlement L=32.9	Maximum Settlement L=25.9

### 5.1.3 maximum vertical load results for pile group (1x4,2x4 3x4):

Figure from (5.17) to (5.22) represent the effect of increase number of pile and diameter in maximum vertical for group 1X4,2x4 and 3X4 the comparison between the Allpile6.5 and manual results showing below for combinations (LC01, LC05, LC11, LC18).

maximum vertical load decrease by 46.67 % and 35.28% with increasing of number of piles for 1x4 ,2x4 and 3X4.

the manual results increase more the All pile6.5 results respectively 2.93%,1.6% and 6.4% for group 1X4,2x4 and 3X4.

## 5.2 Lateral load result:

### 5.2.1 deflection and maximum moment of lateral load for 1x4 group pile results:

Figure from (5.23) to (5.30) represent the effect of increase the pile diameter in deflection and maximum moment for lengths 35.9 ,32.9 and 25.9 m for group 1x4. maximum moment and deflection for back and front pile, also compare with diameters (1.2, 1.4,1.6, 1.8m). the maximum deflections decrease by 33.75% with increase the pile diameters also moment for back increase 7.5%. and front is increase 5.4%. The comparison between results from manual calculations and Allpile6.5 for maximum moment find that the manual maximum moment for back pile increase about 5.9% and 3.8% decrease for front pile about 15.74% and 23.12% from Allpile 6.5 results for LC11 and LC18 respectively.

Figure (5.23) LC05 1X4 group deflection for lateral load, maximum moment lateral for diameter (1.2, 1.4 , 1.6 ,1.8) and lengths (35.9,32.9,25.9) for Allpile results from table (5.23)

Table (5.23)

Diameter	1.2		1.4		1.6		1.8	
Maximum Moment	Back	Front	Back	Front	Back	Front	Back	Front
Lateral load	2.55	2.46	2.75	2.6	2.98	2.76	3.22	2.93
Deflection	0	0	0	0	0	0	0	0

Deflection	4.96	7.3	2.78	4.08	2	2.46	1.61	1.64

### 5.2.2 deflection and maximum moment of lateral load for 2x4 group pile results:

Figures from (5.26) to (5.29) represent the effect of increase the pile diameter in deflection and maximum moment for lengths 35.9 ,32.9 and 25.9 m for group 2x4. maximum moment and deflection for back and front pile, also compare with diameters (1.2, 1.4,1.6, 1.8m). the maximum deflections decrease by 37.59% with increase the pile diameters also moment for back increase 5.39%. and front is increase 4.75%. The comparison between results from manual calculations and Allpile6.5 for maximum moment find that the manual maximum moment for back pile increase about 9.5% and 9.1% decrease for front pile about 7.2% and 16.5% from Allpile 6.5 results for LC11 and LC18 respectively.

Figure (5.26) LC01 2X4 group maximum deflection, for diameter (1.2 , 1.4 , 1.6 ,1.8) for Allpile results from table(5.7)

Deflection	1.94	2.88	0.203	0.199

### 5.3 The results from manual calculation, both software Allpile6.5 and pile group software for 1x4 pile group with load combinations LC01 LC05, LC11, LC18 :

Figure (5.30) represent the comparison of maximum vertical load results from two software program(Allpile6.5 ,pile group) and manual calculation of analysis 1x4 group of pile spacing 6.25 length 25.9 m , the comparison show that the result from Allpile6.5 and manual calculation typically same for all combinations, for pile group just results increase 8.09% for LC18 .

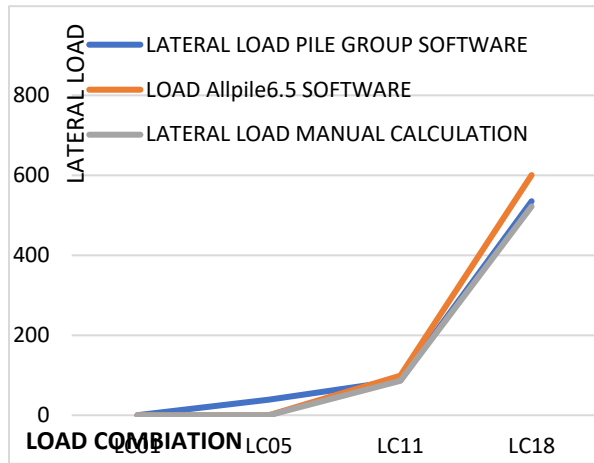

Figure (5.30) represent the comparison of vertical load manual and Allpile6.5 software and pilegroup software results with load combination LC01 LC05, LC11 ,LC18 from table (5.30).

Table  
(5.30)

LC	Maximum vertical load (ALLPILE softwar analysis results)	Maximum vertical load manual calculation	Maximum vertical load (PILE GROUP software analysis results))
LC01	11402.5	11402.5	11400
LC05	11725.03	11725	11706
LC11	11026.31	11026	11024
LC18	10110.35	10110.35	11001

Figure (5.31) represent the comparison of lateral load results, the comparison shows that the result from Allpile6.5 more than manual calculation by 13%, also more than pile group software by 10%.

Table (5.31)

LC	lateral load PILE GROUP software	Lateral load Allpile software	lateral load manual calculation
LC01	0.244	0	0
LC05	38.612	0	0
LC11	87.071	98.9	86
LC18	535.24	600.59	522.25

Figure (5.31) lateral load for manual, Allpile6.5 software and pile group software results with load combination LC01 LC05, LC11, LC18 from table (5.12).

Figure from 5.32 represent the comparison of maximum moment results, the comparison shows that the result from Allpile6.5 more than manual calculation by 44% and 63% LC11and LC18, also more than pile group software by 43% and 90% LC11and LC18.

Table (5.32)

LC	maximum moment pile group software	maximum moment Allpile software	maximum moment manual calculation
LC01	824.18	3.22	0
LC05	791.63	3.22	0
LC11	1965.5	1102.31	612.76
LC18	5226.9	10110.4	3715.8

Figure (5.32) maximum moment for manual, Allpile6.5 software and pile group software results with load combination LC01 LC05, LC11, LC18 from table (5.13).

Table (5.34)

LC	deflection group software	deflectiond Allpile software
LC01	2.25	0.0019
LC05	2.13	0.0019
LC11	9.3	0.269
LC18	4.703	1.64

Figure (5.33) deflection for Allpile6.5 software and pile group software results with load combination LC01 LC05, LC11, LC18 from table (5.14)

Figure from (5.33) represent the comparison of deflection results, the comparison shows that the result from Allpile6.5 less than pile group software by 99% and 65% LC11 and LC18.

A decorative banner with a central rectangular box and two side flaps. The central box has rounded corners and a blue outline. The side flaps are also outlined in blue and have a pointed, arrow-like shape. The banner is centered on the page.

## **Chapter Six**

# **Conclusions and Recommendations**

## Chapter Six

### Conclusions and Recommendations

#### 6.2 Conclusions:

1. Decrease of the length effect on maximum settlement decrease length of pile from 35.9 m to 32.5 m increasing maximum settlement about 14.14%, decrease the length from 35.9 m to 25.9 m increasing maximum settlement about 39.36%, also decrease from 32.9 m to 25.9 m increase the maximum settlement about 31.08% for all diameters for group 1x4.
2. Increase of the pile diameter effect on reduction maximum settlement for length 35.9 m the maximum settlement decrease about 26.43%, for length 32.9 m the maximum settlement decrease about 24.49% and for length 25.9 m maximum settlement decrease about 22.59% for group 1x4 with increasing of diameters.
3. Decrease of the length effect on maximum settlement. decrease length of pile from 35.9 m to 32.5 m increasing maximum settlement about 10.2%, decrease the length from 35.9 m to 25.9 m increasing maximum settlement about 33.1%, also decrease from 32.9 m to 25.9 m increase the maximum settlement about 25.5% for all diameters for group 2x4.
4. Increase of the pile diameter effect on reduction of maximum settlement for length 35.9 m the maximum settlement decrease about 27.2%, for length 32.9 m the maximum settlement decrease about 28% and for length 25.9 m the maximum settlement decrease about 25.85% for group 2x4 with increasing of diameters.
5. The compression between maximum settlement for group 2x4 and 1x4 group shows that maximum settlement for 1x4 less than maximum settlement 2x4 group by 58.06%, 62.63%, 57.53% respectively to length (35.9, 32.9, 25.9 m).
6. Increase number of pile and diameter decrease the maximum vertical load in each pile for (1X4, 2x4 and 3X4) groups. the maximum vertical load on each pile decreased by 54.38% for 1x4 to 2x4, for 1x4 to 3x4 decrease by 64.95% and by 23.16 % for 2x4 to 3x4 group pile.
7. The manual empirical formulas maximum vertical load results increase more than All pile 6.5 results respectively 2.93%, 1.6% and 6.4% for all lengths.
8. Increase of the pile diameter effect on deflection and maximum moment for all lengths for group 1x4. the maximum deflections decrease by 33.75% with increase

- the pile diameters also moment for back pile increase by 7.5%. and front pile is increase by 5.4%.
9. The comparison between results from manual empirical formulas calculations and Allpile6.5 for maximum moment find that the manual empirical formulas maximum moment for back pile increase by 5.9% and 3.8% and decrease for front pile about 15.74% and 23.12% for All pile 6.5 results for Lc11 and LC18 respectively.
  10. Increase of the pile diameter effect on deflection and maximum moment for lengths 35.9 ,32.9 and 25.9 m for group 2x4. the maximum deflections decrease by 37.59% with increase the pile diameters also moment for back pile increase by 5.39%. and front pile is increase by 4.75%.
  11. The comparison between results from manual empirical formulas calculations and Allpile6.5 for maximum moment find that the manual empirical formulas maximum moment for back pile increase about 9.5% and 9.1% and decrease for front pile about 7.2% and 16.5% from Allpile6.5 results for LC11 and LC18 respectively.
  12. The comparison of maximum vertical load results from two software program(Allpile6.5 ,pile group) and manual empirical formulas calculation of analysis 1x4 group of pile spacing 6.25 length 25.9 m , the comparison show that the result from Allpile6.5 and manual empirical formulas calculation typically same for all combinations, for software pile group results increase 8.09% for only LC18 .
  13. The Allpile6.5 lateral load results are more than manual empirical formulas calculation results by 13%, also more than pile group software by 10%.
  14. The Allpile6.5 maximum moment results are more than manual empirical formulas calculation results by 44% and 63% LC11and LC18, also more than pile group software by 43% and 90% LC11and LC18.
  15. The Allpile6.5 deflection results less than pile group software results by 99% and 65% LC11and LC18,
  16. According to the analysis the increase of the length doesn't effect on reduction of deflection or moment, lateral load on pile.
  17. Increase of the diameter of pile reduces the deflection and increase the maximum moment on single pile.
  18. the result of analysis by two software Allpile 6.5 is 2D analysis software and the PILEGROUP is 3D software and the manual empirical formulas calculation for

vertical load analysis is close but for lateral load analysis the result from manual empirical formulas and allpile6.5 is close but the pile group is large compare with the other two ways.

19. The pile group designed 1x4 length 35.9 and diameter 1.8 to support all the load and the pile settlement and deflection in the design range.

### **6.3 Recommendations:**

Based on the results obtained it to recommended:

1. To use manual empirical formulas calculation preliminary studies of pile as single and pile group analysis in order to predict capacity and load subjected to pile for pile design.
2. To use Allpile6.5 software for all final analysis and design of bored piles.

### **For future studies it recommended to:**

1. Analyze pile and group pile using 3D software program.
2. Analyze and design batter pile inside group pile and study the effect that on vertical and lateral load distribution.
3. Analyze and design group pile under earthquake load.

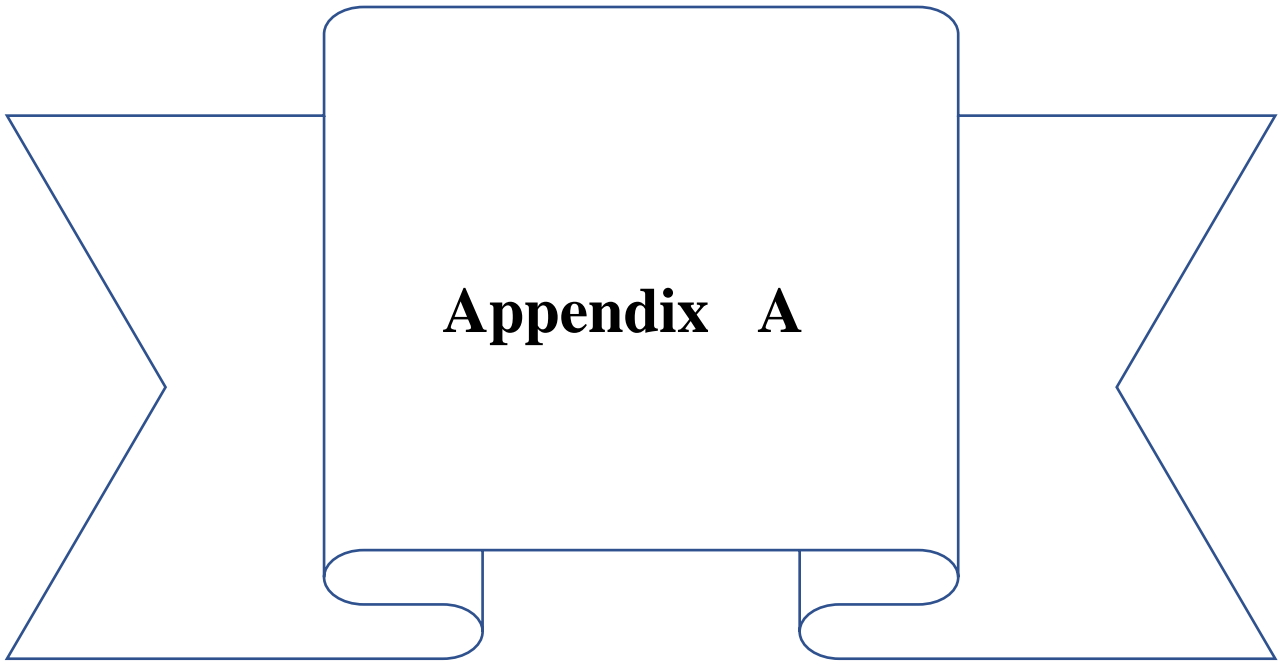

A decorative graphic consisting of a central rounded rectangle with a blue outline. This central box is flanked on both sides by larger, white, arrow-shaped flaps that point towards the center. The flaps have a blue outline and a pointed tip. At the bottom of the central box, there are two small, rounded rectangular tabs that appear to be folded over, with a light gray fill and a blue outline. The word "References" is centered within the central box in a bold, black, serif font.

4. Lateral Analysis:

Try Shear= 0.00 -kN

Deduction factor due to Group Effect, R= 0.45

Fixed Head Condition

Try Results:

Top Deflection,  $y_t = 0.00109$ -cm

Max. Moment,  $M = 2.93$ -kN-m

Top Deflection Slope,  $S_t = 0.00000$

C. Final Results & Summary:

Max. Cap Settlement,  $X_{max} = 1.47383$ -cm

Average Cap Settlement,  $X_{average} = 1.35347$ -cm

Differential Cap Settlement,  $X_{diff} = 0.24072$ -cm

Cap Rotation,  $R_t = 0.005777238$  Slope

Cap Rotation,  $R_a = 0.33100766$  Degree

Lateral Cap Movement (Deflection),  $y_t = 0.000$ -cm

Front Pile: Shear = 0.00-kN

Back Pile: Shear = 0.00-kN

Lateral Cap Movement,  $y_t = 0.000$ -cm, OK with the Allowable Deflection = 2.500-cm

Max. Cap Settlement,  $X_{max} = 1.474$ -cm, OK with the Allowable Deflection = 2.500-cm

X-Direction (Lateral Loading in X Direction)

\*\*\*\*\*

$N_x < 2$ , No Calculation. Please run single or tower pile analysis.

Note: If program can't find result or the result exceeds the up limits. The result shows 9999

Notes:

Q - Vertical Load at pile top

P - Lateral Shear Load at pile top

M - Moment at pile top

$X_{all}$  - Pile top total settlement

$y_t$  - Pile top deflection

$S_t$  - Pile top deflection slope (deflection/unit length)

The Max. Moment calculated by program is an internal moment of shaft due to the loading. Engineers

have to check whether the pile has enough moment capacity to resist the Max. Moment with adequate

factor of safety. If not, the pile may be damaged under the loading.

### BrinchHasen method spraed sheet for diameter 1.6m

BrinchHasen method spraed sheet for dimater 1.6m

Height of application above top of pile 5.9 m  
 Length of pile 20 m  
 Pile diameter 1.6 m  
 Depth about which rotation of pile occurs (use negative numbers) -15.1 m  
 Number of slices **top soil** 10  
 Depth of top soil 9 m  
 Number of slices **bottom soil** (max 10) 10

**Soil Properties**

**Upper soil**  
 Phi 21 degrees  
 c' 0 kN/m<sup>2</sup>  
 rate of change of c' 0 kN/m<sup>2</sup>/m  
 Gamma 8 kN/m<sup>3</sup>

**Bottom soil**  
 Phi 40 degrees  
 c' 0 kN/m<sup>2</sup>  
 rate of change of c' 0 kN/m<sup>2</sup>/m  
 Gamma 9 kN/m<sup>3</sup>

Height of each element in top soil 0.9  
 Height of each element in bottom soil 1.1

**Resistance to Horizontal Force = 9039.5 kN**

The graphic consists of a central rounded rectangle with a blue outline. On the left and right sides, there are chevron-shaped elements pointing towards the center, also with blue outlines. At the bottom, there are two small, rounded rectangular tabs extending downwards, suggesting a page or document edge. The text "Appendix B" is centered within the main rectangle in a bold, black, serif font.

**Appendix B**

## Soil report recommendations

PROJECT: SOBA BRIDGE  
DATE : DECEMBER 2011

11

- The prevailing sub-soil conditions.
- The magnitudes of loads imposed by the superstructures.
- The total and differential tolerable ground settlement under the foundation.
- The economics of alternative foundation design, and
- The capability and experience of available foundation construction contractors.

Taking these factors into account with reference to particular project under consideration, the bored concrete pile foundation type is recommended to support the proposed bridge at the investigated site:

#### 6.1- Pile foundation:

Consideration has been given to the use of bored piles as a feasible foundation alternative at this particular site. These are suitable for the rock formation encountered at the present site. The bored piles have the advantage that local contractors are available. Piles of 60 to 120 cm diameter are recommended. The length of the pile will depend on the magnitude and direction of the forces acting on the pile and the soil conditions within the pile zone. The piles should rest on or be embedded into the Nubian sandstone formation at the depth of 30.0 m below the existing ground level or the river bed.

The allowable bearing capacity of individual bored pile was calculated according to *AllPile* software program and a summary of the computed safe pile's bearing capacity is given below for piles of variable diameters and 30.0m length.

Table(4) : Pile allowable bearing capacity

Pile diameter (m)	0.6	0.8	1.0	1.2
Pile embedment (m)	30.0	30.0	30.0	30.0
Allowable bearing Capacity (kN)	3000	4900	7100	9500

PROJECT: SOBA BRIDGE  
DATE : DECEMBER 2011

12

#### 6.2- General Recommendations:

- Depending on the magnitudes of anticipated superimposed loads, the appropriate size of pile (length, cross-section or diameter) and the number and spacing of piles in each group may be decided according to the foundation design method applied.
- Bored piles are normally constructed by advancing a hole of appropriate size to the required depth by auger drilling, or any other suitable technique followed by lowering down the reinforcement cage and gradually filling the hole with concrete. Below the groundwater level or in the offshore sub-structure trimme pipes or casings should be used.
- It must be pointed out that only static vertical bearing capacity, using factor of safety of 3 for end bearing and 2.5 for side friction, of the piles were considered in the analysis and thus the values given above should be considered as estimates and guideline for foundation design. To confirm the theoretical calculations of the allowable bearing capacity of single piles, it is strongly recommended that few pile-loading tests be carried out. The pile load test should be carried out on a typical pile loaded to a minimum of 1.5 times the calculated design load.

#### 7.0- Conclusions and Recommendations:

The site investigation has been made for (A&A for Urban Development) at Soba town, in Khartoum state for the proposed Soba Bridge. A total of ten (10) boreholes ranging between 40 to 50m, as suggested by the client, were drilled in this project. Field as well as laboratory tests were conducted on the soil samples and the summary of the results are presented in this report. The results indicated that the site is dominated by alluvial soils that are followed by Nubian formation towards the bottom of the boreholes. The alluvial deposits are clayey silt (ML), silty clay (CL), clayey sand (SC) and silty sands (SM, SP-SM, or SP), whereas the Nubian formation is comprising of sandstone and mudstone. The chemical test results indicated alkaline soils free from harmful
