

DEDICATION

To the Great prophet Mohammed

(Peace and prayers be Upon him),,

To my big family (father, mother, sisters and brother),,

To my small Family, my Husband and Children,,

To my friends in Range and Pasture General,, Directorate

To you,,

Fatima Siddiq Alhadi Mohammed

ACKNOWLEDGMENT

Firstly I thank Allah, The merciful and gracious for giving me the health and power to complete this study. Secondly I would like to thank Dr. Mohammed Ibrahim Abdelsalam my supervisor for his valuable suggestions in putting out the broad line of this research. Great thanks to the Ministry of Animal Recourses- Range and Pasture general Directorate for giving me valuable opportunity for M.Sc. study. My gratitude and recognitions to Dr. Gallal Abaas for his valuable help and endless patience in data analysis. I would also like to thanks individual experts, Dr. Sawsan Kharalseed, Mr. Mohammed Fadalalmowla, Mr. Abdalrahman Mahmud who provided their valuable time to enhance this study with their suggestions. Deeply appreciation and thanks to (my husband) Dr. gammereldien Abdalrahman Ibrahim for his continuous support all the time and helped. I thanks due to local communities who deal with pastoralism and Mining activities in Butana area. I would also like to thanks all the staff of Butana Integrated Rural Development Project and all the respondents in Al-Tkoon, Abogola, Al-Rbdaa and Al-Bogaa villages for their welcome reception and provision of necessary information in both socio-economic and Rangeland Measurements. Special thanks to my close friend Amna Esmail for her moral support and to all my colleagues in Range and Pasture General Director.

ABSTRACT

This study was conducted in Al-Sobag area at Gedarif State-Sudan in October 2018. The study aimed to assess the impacts of gold mining on rangeland vegetation and socio-economic aspects of local communities. The study area was chosen as a range site representing these rangelands affected by gold mining. Two range sites were selected (Site A) that affected by gold mining activities and (Site B) did not affected in the same zone. Each site was divided into four plots were selected randomly. Four lines transects with a specific angles used compass at each range site, to estimate vegetation attributes and soil seed bank. The socio-economic data were collected through general survey, observations and questionnaire. Four villages namely (Al-Bougaa- Al-Rbdaa Abogola and Al-Tokoon) were selected randomly from the total villages surrounding the mined sites. A total of 60 Households randomly selected which constituted about 10% of the total number of households in these villages, which approximately about (600) families. Data were analyzed for vegetation attributes; organized, tabulated and analyzed using standard range measurements equations. All data tested by statistical analysis by using (SAS) program using (ANOVA) and Duncan procedure, to compare differences in vegetation attribute and seed bank in the two areas. The socio-economic data were analyzed using the Statistical Package for Social Sciences (SPSS) software (Ver. 20.0) by computing descriptive statistics. The main findings of this study according to the vegetation attributes showed that there were significant differences between percentages of ground cover in terms of bare soil, rocks, litter and plant cover in the location close to the mining activities, there are increased in the proportion of bare soil (56.37%) compared to the plant cover (2.25%). While there are no significant differences between the components of ground cover in the range site which is far from the mining area. Beside that the affected range site by gold mining activities was recorded the same percentage of live and dead seeds (50%), while the unaffected range site was recorded (31.6%) and (68.4%) for live and dead seeds respectively. The findings of socio-economic aspects results indicated that about of (58.3%) respondents within the active mining sites agreed that there are negative impacts of gold mining exploitations on soil of rangeland. Also the study revealed that about (95%) of respondents agreed that gold mining activities affected negatively on the animal correlated the problems facing livestock and (85%) they said that the mining exploitation had impacted negatively in human health. The study concludes that the increase of bare soil percentage, vegetation cover retrogression and decrease biomass productivity and range carrying capacity in the study range sites were main range condition

indicators of the impact of gold mining in these rangelands. The majority of respondents (61.7%) said the rangelands were deteriorated after gold mining appeared in Al-Sobag area. Therefore, the study recommends that: The implementation and integration of best practices for environmentally responsible extraction of gold from mining sites could also reduce the adverse effects of artesian gold mining on natural resources. Rehabilitation efforts are required to overcome the impacts of gold mining activities on sustainable range land management, and reseeding the range sites with the desirable plant species.

المستخلص

أجريت هذه الدراسة في منطقة الصباغ بولاية القضارف - السودان في أكتوبر 2018. هدفت هذه الدراسة إلى تقييم آثار تعدين الذهب على الغطاء النباتي للمراعي الطبيعية ودراسة الجوانب الاجتماعية والاقتصادية للمجتمعات المحلية. تم اختيار موقعين (أ) المتأثر بأنشطة تعدين الذهب و الموقع الآخر (ب) غير متأثر بالتعدين في نفس النطاق البيئي بمنطقة الصباغ بصورة عشوائية ومن ثم تم تحديد أربعة خط عينة (Transect) بزوايا محدد باستخدام البوصلة، كل خط عينة (زاوية) يتم تقسيمه الي خطين 100 متر كخط عينة أول ثم تترك مسافة 100 متر كفاصل دون قياسات ثم 100 كخط عينة ثاني ليصبح طول خط العينة 300 متر، لتقدير الغطاء النباتي ومخزون البذور في التربة. جمعت البيانات المتعلقة بالتعدين عن الذهب وتأثيرها على الجوانب الاجتماعية والاقتصادية للأسر من خلال المسح العام والملاحظات والاستبيان. اختير عدد أربعة قرى بصورة عشوائية وهي (البقعة - الرداء - التكون وأبوجوله) من مجموع القرى المحيطة بالمواقع المتأثرة والتي شملت عدد 60 أسرة والتي تمثل حوالي 10 ٪ من مجموع عدد الأسر في هذه القرى حيث بلغت 600 أسرة. تم تحليل البيانات الخاصة بالغطاء النباتي من خلال برنامج التحليل الإحصائي (SAS) باستخدام طريقة (ANOVA) و Duncan ، لمقارنة الاختلافات في الغطاء النباتي ومخزون البذور في الموقعين وتمت مقارنة الفروقات. كذلك تم تحليل البيانات الاجتماعية والاقتصادية باستخدام برنامج الحزمة الإحصائية للعلوم الاجتماعية (SPSS) (الإصدار 20) عن طريق حساب الإحصاءات الوصفية. تم عرض تحليل النتائج في شكل تكرارات ونسب مئوية بالإضافة للمخططات والرسوم البيانية والجداول. أظهرت النتائج الرئيسية لهذه الدراسة أن هنالك فروقات واضحة في نسبة التغطية من حيث التربة العارية والصخور وبقايا النباتات والغطاء النباتي في الموقع المتأثر بالتعدين، وهناك زيادة في نسبة تربة العارية (56.37٪) مقارنة بالغطاء النباتي (2.25٪)، بينما لا توجد فروقات معنوية في التغطية الأرضية بالموقع البعيد عن منطقة التعدين. إلى جانب ذلك سجل الموقع المتأثر بتعدين الذهب نفس نسبة البذور الحية والميتة والتي بلغت (50 ٪)، بينما الموقع غير المتأثر بالتعدين سجل (31.6 ٪) و (68.4 ٪) للبذور الحية والميتة على التوالي. النتائج الرئيسية الجوانب الاجتماعية والاقتصادية تشير أن حوالي (58.3 ٪) من المستجوبين اكدو وجود تأثيرات سلبية للتعدين على تربة المراعي. كما أوضحت الدراسة أن حوالي (95 ٪) من المستجوبين أن تعدين الذهب أثر سلباً على الحيوانات بينما (85 ٪) منهم أوضحوا أن استغلال التعدين قد أثر سلباً على صحة الإنسان بالمنطقة. خلصت الدراسة إلى أن زيادة نسبة التعرية وتراجع الغطاء النباتي وانخفاض إنتاجية الكتلة الحيوية والحمولة الرعوية في الموقع الرعوي هي مؤشرات رئيسية

تأثير تعدين الذهب مراعي المنطقة. غالبية المستهدفين بنسبة (61.7%) أكدوا أن المراعي تدهورت بعد ظهور تعدين الذهب في منطقة الصباغ. ولذلك، توصي الدراسة بتوحيد وتنفيذ أفضل التقنيات في عمليات إستخراج الذهب للمحافظة علي البيئة بمواقع التعدين والتي بدورها تتعكس علي الموارد الطبيعية بالمنطقة. كما يجب العمل علي إعادة تأهيل المواقع المتأثرة للتغلب علي الانشطة الخاصة بالتعدين للوصول الي إدارة سليمة ومستدامة من خلال إعادة الاستزراع بالنباتات الرعوية المرغوبة وذات القيمة العالية غذائيا وبيئيا.
