

DEDICATION

This work is dedicated to my parents, wife, sons, brothers, sisters and everyone who straggly defends to keep environs clean.

DECLARATION

I hereby solemnly declare that the work presented in this thesis is my own work and that, to the best of my knowledge, it contains no material previously published or written by another person and has not been previously submitted to any University or educational institute for an academic qualification or any other degree. The work I am submitting does not contravene any copyright.

ACKNOWLEDGEMENT

I would like to express sincere gratitude to my supervisors Dr. Ahmed M. A. Eldoma and Dr. Mohamed Elgameri for their guidance, kind support and useful suggestions to bring the research into shape right from designing of research proposal till the finalization of the thesis. I have gained a lot of scientific experiences from them.

My thanks go to Dr. Mamoun Osman and Dr. Mahagoub Suliman for their continuous help and precious advices specially, in remote sensing techniques.

It is my great pleasure to thank the authority of El-malha locality for their support and assistant during field data collection. Also I wish to record my sincere thanks and appreciation to team work group (Ahmed Ishag, Mahmoud Ahmed, Zakaria Khabish, Elhadi Omar, Adam Idris, Hassib Hamid, Mohamed Abdella and Salih Guma) for their assistant during field data collection.

I would like to express my sincere thanks to the entire staff at Faculty of Forestry and Range Science, Sudan University of Science and Technology.

Also I am thankful to the entire colleagues at the faculty of Environmental science and natural resources, El- fashir University, for their kind support and encouragement. Also my thanks extend to Dr. Ismail Fangama for his help and inspiration.

Last but not least, my everlasting gratitude goes to my beloved wife Bidour, dearest son Mohamed, and daughter Heba for their patience to my long absence, brothers, sisters, relatives and friends who always encouraged me and wished me success. Finally, I would like to greet my parents for their blessing to accomplish my degree.

ABSTRACT

This study was conducted in the Meidob Hills area of El-malha locality about 170 km north El-fasher, North Darfur State. The main objective of the research was to study and describe the quantitative changes in tree composition, structure and species richness as well as to explore the impacts of anthropogenic and environmental factors. In addition, the study attempted to detect the nature of changes affected in structure and composition of the tree species as a consequence of both increased human exploitation and microclimatic effects during the period (1995- 2010) using remote sensing.

The ecological field data for the present work were collected during the period 2010 to 2011. A pilot survey was first conducted to gather enough information which has been used to decide upon the sampling procedure and intensity. Based on the results of the pilot survey, a full inventory was

then designed and executed using a stratified sampling procedure. Thirty four 34 sample plots of one ha sample size each (56.43 m radius) were laid down. Subplots of 0.25 ha (28.21 m radius) were laid down in the center of each sample plot for regeneration studies. Measurements were made to record diameter and height of all trees having a diameter ≥ 6 cm within each sample plot. A regeneration count was then conducted inside the subplots.

The findings revealed that the total sampled population in the study area amount 922 trees, comprising ten species within seven families giving a stocking density of 27 trees per ha. The regeneration count registered a total number of 13 seedlings per ha for all species.

Species wise analysis indicates *Acacia tortilis* subsp. raddiana was the most ecologically dominant species contributing a high importance value index (IVI) of 92.21 %.

The landsat TM image of April 1995 and June 2008 were analyzed using Erdas Imagine software to unveil tree species change detection of the study area. Visual interpretation and digital image processing was applied to process the imagery for determining land cover classes. In addition, post-classification change detection methods were used to detect changes in land cover classes.

After performing unsupervised classification on these images, a total of four land cover classes were identified and

mapped. These were Hills and basement, sparse trees and shrubs, bare land and grassland. An NDVI calculation was made on these images and vegetated areas were identified.

The results of the analysis revealed that from 1995 to 2008 the tree cover has decreased by 3847 ha representing 10 % of the total area. These changes were attributed directly to environmental and anthropogenic factors viz. desertification, drought, illegal cutting of trees for fire wood, building material, agriculture expansion and overgrazing. The field work and remote sensing data were supported by a socioeconomic study through which data collected by using a questionnaire. Information including major indicators for degradation, reasons behind land degradation, useful tree species in the area, and major causes for forest destruction in the area were gathered from local people.

Lessons learned from the use of satellite imagery data and remote sensing techniques in the present work proved to be effective, reliable, suitable and valuable tool for detection, prediction and identification of forest cover change in such degraded areas of arid and semi arid regions under risk.

خلاصة الدراسة

أجريت هذه الدراسة بمنطقة جبال الميدوب، محلية المالحة بولاية شمال دافور والتي تبعد حوالي 170 كم شمال مدينة الفاشر حاضرة الولاية.

والغرض الاساسي من هذا البحث هو دراسة ووصف بعض التغيرات التكوينية والبنوية للمجاميع والأنواع الشجرية لبيان بعض المؤشرات البيئية و الإنسانية. أيضاً لرصد طبيعة التغيرات التي تؤثر في الخصائص التكوينية والبنوية للمجاميع الشجرية كنتيجة لزيادة أنشطة الإنسان وظروف المناخ الموضوعي للمنطقة خلال الفترة من (1995- 2008) باستخدام تقنية الإستشعار عن بعد.

تم جمع المعلومات البيئية الحقلية لهذه الدراسة خلال الفترة 2010 م. اولاً اجري مسح إستكشافي لمعرفة كيفية وطبيعة المنطفة وجمع المعلومات التي تساعد في عملية اختيار العينة. بناءً علي نتائج المسح الأولى تمت تنفيذ عملية الحصر كاملاً باستخدام طريقة العينة الطبقية العشوائية، و أخذت 34 عينة دائرية الشكل بمساحة هكتار واحد لكل عينة (نق = 56.43 م). كما أخذت عينة جزئية بمساحة 0.25 هكتار (نق = 28.21 م) في مركز كل عينة كاملة. وقد تم قياس المعلومات الحقلية لكل عينة والمتمثلة في أقطار الأشجار عند مستوى الصدر وأطوال الأشجار التي أقطارها 6 سم فأكثر. و كذلك تم عدّ التجديد الطبيعي في كل عينة جزئية.

لقد أظهرت نتائج هذه الدراسة أن حوالي 922 شجرة ذات أقطار 6 سم فأكثر و 10 أنواع شجرية و 7 عائلة شجرية تم التعرف عليها وعدّها في المنطقة الممسوحة. و بلغت عدد الأشجار في الهكتار حوالي 27 فقط شجرة بالنسبة لكل الأنواع. أما التّجديد الطبيعي فكانت حوالي 13 نبتة فقط في الهكتار الواحد لكل الأنواع.

ومن خلال نتائج تحليل أنواع الأشجار الموجودة في المنطقة حيث تشير الدراسة إلى أنّ شجرة السيال هي الأكثر سيادة ايكولوجيا في المنطقة وبلغت ال 92.21 Importance value index %.

كما تم تحليل صور الأقمار الصناعية لأندسات 5 (Landsat) إبريل 1995 ويونيو 2008 باستخدام برنامج المعالجة (Erdas Imagine) لرصد التغير

في الأنواع الشجرية في منطقة الدراسة. أيضاً تم استخدام التحليل والتفسير البصري ومعالجة الصور الرقمية، وذلك لتحديد أصناف غطاء الأرض. بالإضافة لذلك استخدم التصنيف المتقدم لإظهار التغيرات في أصناف غطاء الأرض.

بعد تصنيف الأقمار الصناعية التصنيف غير المراقب ، تم التعرف علي أربعة أصناف من غطاء الأرض وهي: الجبال و الصخور، الأرض الجرداء، الأشجار المتفرقة والشجيرات وأراضي الحشائش. بالإضافة إلى ذلك تم حساب مؤشر الفرق العام للغطاء النباتي (NDVI) في صور الأقمار الصناعية و تم التعرف علي مواقع الغطاء النباتي علي الصور.

ولقد أظهرت نتائج هذه الدراسة خلال الفترة من 1995 إلى 2008 ، أن الأشجار تقلصت مساحتها ب 3847 هكتار تمثل 10 % من المساحة الكلية لمنطقة الدراسة. وهذه التغيرات حدثت نتيجة للأنشطة الإنسان في المنطقة المتمثلة في : القطع غير القانوني للأشجار لاستخدامه كحطب حريق، ومواد البناء، والتوسع الزراعي التقليدي في مساحات شاسعة، والإفراط الرعوي. بالإضافة إلى عوامل بيئية مثل الجفاف، و التصحر التي اجتاحت المنطقة في فترات متعاقبة.

أيضاً جمعت المعلومات الخاصة بالنواحي الاجتماعية الاقتصادية لإنسان المنطقة أثناء العمل الميداني باستخدام الاستبيان كمعلومات مساعدة لدعم المعلومات الحقلية وبيانات الإستشعار عن بعد. حيث تتمثل المعلومات في : مؤشرات التدهور، وأسباب تدهور الغطاء الشجري، والأشجار الأكثر أهمية في المنطقة.

الدروس المستفادة من استخدام بيانات صور الأقمار الصناعية وتقنيات الإستشعار عن بعد في هذه الدراسة أثبتت أنها اداة قيمة/ فعّالة في عملية الرصد، والتنبؤ والتعرف علي التغير في الغطاء الغابي في المناطق الجافة وشبه الجافة المهددة بالتدهور.
