# Dedication

This work is dedicated to:

The souls of:

My father Buony.

My mother Nyaluak.

My brother Thir.

Also to:

My wife Dr. Grace John Gatlouk.

My kids Goy, Nyaboul, Challing and Billit.

And my brother's kids.

Sabit, Deng and Nyaluak.

# Acknowledgement

From my adhering moral to thank; really I am very grateful to Dr. Muzzamil Atta Ali, the supervisor of this research; who had always been very generous to see me in his office and at home and I was very lucky to learn from him what I could never attain by myself in years.

I would also like to extend my thanks to Dr. Mohamed El-Tayeb Hamed; my co-supervisor for his on-going help and support and special thanks are due to professor Usama Elsheikh; professor Ali Saad and Dr. Mohamed Tag El-din in the department of animal production Sudan University of Science and technology. My thanks also go to father in law Rev. John Gatlouk, my nephew Mr. Dak Doup, for their great help and concern.

My warm thanks are also extended to the members and the administration staff of the Department of Animal Production – Military Cooperative Corporation “Kafari – Khartoum North” who used to show great hospitality and for allowing me to conduct my research experiment and collecting data as well.

I also need to mention the help given to me by my close friend Tarig M. Badri who took the burden of fist typing, last draft, analyzing and finalizing the research. The man is really very special; my thanks are extended to his family.

Finally, it is worth mentioning that, researchers should keep in mind that, we should always care about our relatives and friends as we care about our studies because the researcher found that such people remain faithful and close to him in sticky situations. To those kind-heart people who never ceased encouraging me under different circumstances, "secrets of struggling for survival"; I extend them my thanks and regards. Above all, God alone has wisdom, regards, and knowledge.

***Maluit Buony Deng; March 2010 Khartoum - Sudan.***

## Abstract

Two experiments were carried out to investigate the effects of season of calving, year of calving and parity order of Kenana × Friesian crossbreed cows on milk yield and lactation curve components using the model ( $y=an^b.e^{-cn}$ ). The evaluation of the udder measurements of crossbreed dairy cows in the Sudan was also aimed. The study was carried out in Kafori Military Corporation Farm for Animal Production. The first experiments concerned with milk production performance (total milk yield, lactation length, persistency index) and lactation curve components which include: initial milk yield, rate of increase to the peak yield, rate of decrease from the peak yield, the peak yield of week, the peak yield and the persistency of lactation curve. The data were extracted from the farm records of the period between 2000 to 2006 years. The records were arranged according to season of calving into summer season (March to June), wet season (July to October) and winter season (November to February). The data were also classified in to 7 year groups (one year for each group). The records were also grouped into their parity order (group) parities. The second experiment concerned with the investigation of the correlation between total milk yield and udder measurements. Cows of the farm were classified according to their number of parties (1-8 parities). The cows were also grouped in to three lactations stage groups: early lactation stage, mid lactation stage and late lactation stage. The milk yield and udder measurements were taken before and after each milking (morning and evening milkings). The parameters of udder measurement were: udder circumference, udder length, udder width, fore udder depth, hind udder depth and udder capacity. The data for the first experiment were test by 3 way analysis of variance to examine the significant of effects of year and season of calving and the cow's parity order on the milking performance traits and the lactation curve

components. The data of the second experiment were tested also by (3 way analysis) of variance to test the significance of effects of cows' parity order, the stage of lactation and time of milking on the udder measurements and milk yield. The regressions of milk yield on the different udder measurements were also tested. The mean total yield of the crossbred Kenana X Frisian was  $5078.47 \pm 1366.24$  kg, lactation of 27% coefficient of variation. The lactation length was  $389.22 \pm 42.81$  days of 11% coefficient of variation, the weekly peak milk yield was  $151.31 \pm 42.12$  kg/week of 28% coefficient of variation and the persistency was  $61.25 \pm 9.26\%$  of 15% coefficient of variation. The results also revealed that season and year of calving and parity order had no significant effect on all of the studied lactation performance traits and the lactation curve components except the total milk yield that was observed to increase significantly with parity order and the persistency of the lactation curve that was significantly low in the 8<sup>th</sup> parity order. Experiment two results showed that the udder measurements were significantly higher before the morning milking than before the noon time milking. The early stage of lactation showed the highest udder measurements whereas the lowest ones were observed at the late stage of lactation groups. All of the studied udder measurements were found to increase significantly with parity order of the cows. The study concluded that the managerial system practiced in the farm relief the cow productivity from the seasonal stress; however the annual changes in these systems as well as the age of cows should be considered when evaluating the milking performance of these crossbred cows. The study also concluded that when evaluating the udder shape and measurements factors such as period between milkings, stage of lactation and cows' age should be put into consideration. It is worth mentioning that the length of the udder before milking is the most udder measurement variable with milk yields. Therefore it can be used with good

accuracy to predict milk yield. Addition of other measurement into multiple regression or use udder capacity may not add more precise prediction.

## ملخص الاطروحة

اجريت هذه الدراسة لاختبار تأثير موسم الولادة، سنة الولادة ورقم الولده على خصائص انتاج اللبن و مكونات منحنى الادرار لابقار الهجين (كنانه x فريزيان) باستخدام النموذج الرياضي  $(y=an^b \cdot e^{-cn})$ . هدفت الدراسة ايضا لتقييم قياسات الضرع وعلاقتها بادرار اللبن. في هذه الدراسة اجريت تجربتين في مزرعة المؤسسة التعاونية العسكرية للإنتاج الحيواني. كانت التجربة الأولى معنية بأداء إنتاج الحليب (الكمية الكلية للبن المنتج ، وطول مدة الحليب ، ومؤشر مثابرة الانتاج) ومكونات منحنى الادرار والتي تشمل: إدرار الحليب الابتدائي ، ومعدل زيادة الانتاج إلى الذروة ، ومعدل انخفاض الانتاج من الذروة ، اسبوع ذروة الانتاج، وكمية الانتاج عند الذروة ومدى مثابرة ذروة منحنى الادرار. استخدمت سجلات إنتاج اللبن الأسبوعية للفترة بين 2000 - 2006 . رتب بيانات الانتاج وفقا لموسم ولادة البقرة (صيف و خريف و شتاء) كما قسمت البيانات حسب سنة الولادة الى ثمانية مجموعات ايضا قسمت هذه السجلات حسب ترتيب الولادة الى ثمانية (1 - 8 ولدات) مجموعات. كانت التجربة الثانية معنية بدراسة العلاقة بين كمية الادرار وقياسات الضرع. وفيها تم تقسيم الابقار الموجودة في المزرعة الى ثلاثة مجموعات حسب مرحلة الحليب (مبكرة، متوسطه و متأخره). كما قسمت ايضا الى حسب ترتيب الولادة الي 8 مجموعات. تم جمع بيانات انتاج اللبن وقياسات الضرع (محيط الضرع ، وطول الضرع ، وعرض الضرع ، وعمق الضرع الامامي ، وعمق الضرع الخلفي وسعة الضرع) قبل وبعد حلبتي الصباح الظهر. من أجل التجربة الاولى استخدم تحليل التباين ثلاثي الطريق لاختبار معنوية آثار سنة وموسم الولادة وترتيب الولادة صفات أداء الادرار ومكونات منحنى الادرار. بيانات التجربة الثانية تم اختبارها أيضا بتحليل التباين ثلاثي الطريق لاختبار معنوية آثار ترتيب الولادة ومرحلة الادرار ووقت الحليب على قياسات الضرع وانتاج اللبن. كما تم اختبار انحدارات انتاج اللبن على قياسات الضرع المختلفة. كانت قيم انتاج اللبن الكلى وطول فترة الادرار وكمية الانتاج الاسبوعي عند الذروة و نسبة مثابرة الادرار  $1366.24 \pm 5078.47$  كجم ب 27 % معامل اختلاف ،  $42.81 \pm 398.22$  أيام 11 % معامل اختلاف و  $151.31 \pm 42.12$  كجم / الأسبوع ب 28 % معامل اختلاف و  $61.25 \pm 9.26$  % ب 15 % معامل الاختلاف على التوالي. وأظهرت النتائج ان موسم وسنة الولادة وترتيب الولادة لم يكن لها تأثير معنوي على جميع صفات أداء الادرار ومكونات منحنى الادرار باستثناء الانتاج الكلي للبن الذي لوحظ زيادته المعنوية مع ترتيب الولادة ومثابرة منحنى الادرار التي كانت منخفضة معنويا في ابقار مجموعة الولادة الثامنة. أظهرت نتائج التجربة الثانية ان قياسات الضرع أعلى معنويا قبل حلبه الصباح من قبل حلبه الظهر. في مرحلة الانتاج مبكرة كانت قياسات الضرع الأعلى معنويا في حين الاكثر انخفاضا لوحظت في المرحلة المتأخرة من الادرار. كل القياسات الضرع التي درست تزيد معنويا مع زيادة ترتيب الولادة. وخلصت الدراسة إلى أن نظام الرعاية الذي يمارس في المزرعة يحمي إنتاجية البقرة من الإجهاد الموسمي ، إلا أن التغيرات السنوية في هذه النظم ، فضلا عن عمر الأبقار ينبغي أخذها في الاعتبار عند تقييم أداء هذه الأبقار الهجين. وخلصت الدراسة أيضا أنه عندما تقييم شكل الضرع وقياساته عوامل

مثل الفترة بين الحلبتين ، ومرحلة الادرار وعمر الابقار ينبغي أن توضع في الاعتبار. و الجدير بالذكر أن طول الضرع قبل الحلب هو أكثر قياسات الضرع تغيراً مع كمية الادرار لذا يمكن استخدامه بدقة جيدة للتنبؤ بكمية الادرار. إضافة قياس آخر في انحدار متعدد أو استخدام سعة الضرع قد لا يضيف دقة أكثر للتنبؤ .
