Dedication

TO My parents

To My brothers

To my friends

Acknowledgments

Firstly the grateful thanks to Almighty Allah, the lord of earth and skies for completing this research. I would like to express my thanks and appreciations to my supervisor Dr. Abdelbagi Elnagi Mohamed, College of Medical Laboratory Science, Department of Microbiology, Sudan University of Science and Technology for his unfailing patience, expert advices, supervision, guidance, efforts, suggestions and his valuable time.

Extended thanks to The staff of the College of Medical Laboratory Science, especially Dr. Mohammed Siddig, Ustaz Aboalgasim Abbas, Ustaz Yaseen.A.Omer, Ustaza Samer.M.Shareef , Ustaz Ahmed.A.Galander, Ustaz Amged Abdelkareem, Ustaza Asged.M.Mokhtar, Ustaza Maryam Abbas , Ustaza Sarah.O.Yousif , Ustaza Samia.M.Ahmed, Ustaza Altaf Suleman , Ms. Nafeesa Mohamed, Mr. Mohamed.A.Alsaied and Mr. Fawzy Ibrahim for their help and cooperation and encouragement.

A special thanks to Ms. Suhair Ramadan for her grateful efforts and valuable advices.

A lot of thanks to The Medical Laboratory staff of Omdurman Teaching Hospital, Khartoum North Renal Center and Ibn Sina Specialized Hospital for their cooperation help and support.

I would like to express a special word of thanks to my colleagues, friends and students.

My deepest appreciation to everyone who helped me in collection of my specimens, Mr. Modether.O.Abdelbaseer, Ms. Suhair Abdelsatar and those in hemodialysis units of Omdurman Teaching Hospital (in specific Youhanez and Omer), Khartoum North Renal Center and Ibn Sina Specialized Hospital.

My heartiest thanks to my parents in supporting me and who have been the source of encouragement and inspiration throughout my life.

I am also very grateful to my aunt Nora Osman, for her motivation and support.

I thank all the patients for their cooperation and participation and to whom I am greatly indebted.

Abstract

The main aim of this study was to determine the seroprevalence of human cytomegalovirus (HCMV) antibodies (IgG and IgM) using Enzyme-Linked Immunosorbent Assay (ELISA), among 160 hemodialysis patients and 40 apparently healthy control in Khartoum State. Hemodialysis patients in this study were selected from Ibn Sina Specialized Hospital, Khartoum North Renal Center and Omdurman Teaching Hospital. Of the 160 dialysis patients 107 were males (65.6%) and 53 were females (33.1%) and their ages ranged from 14 to 90 years. The subgroups of hemodialysis patients were, 110 hepatitis-negative (68.8%), 26 HBV-positive (16.3%) and 24 HCV-positive (15.0%). Out of the 40 control subjects, 19 were males (47%) and 21 were females (53%) and their ages ranged from 14 to 73 years. The prevalence of CMV antibodies was high among both the hemodialysis patients (98.12%) and the control group (100%). While 157 hemodialysis patients were anti-CMV IgG positive (98.12%), only 3 were negative (1.88%). Among different hemodialysis patients subgroups, 108 hepatitis-negative (98.2%), 26 HBV-positive (100%) and 23 HCV-positive (95.5%) were positive to anti-CMV IgG and there was no significant difference ($p > 0.05$) between them. It was found that 105 males (98.13%) and 52 females (98.11%) were anti-CMV IgG positive and there was no significant difference ($p > 0.05$) between both genders. In contrast, all 40 control subjects (males and females) were positive for anti-CMV IgG (100%). Out of the 11 anti-CMV IgM positive dialysis patients (6.9%) 5 were hepatitis-negative (45.5%), 4 were HBV-positive (36.4%) and 2 were HCV-positive (18.2%) and there was no significant difference ($p > 0.05$) between them. The study also found that 8 males (72.7%) and 3 females (27.3%) were anti-CMV IgM positive and there was no significant difference ($p > 0.05$) between them. In addition, out of the 11 control subjects 4 males (36.4%) and 7 females (63.6%) were anti-CMV

IgM positive (27.0%) and there was no significant difference ($p>0.05$) between them. Furthermore, this study found that the main risk factor for primary or past infection of CMV was aging and for secondary infection or reinfection or reactivation of virus was blood transfusion. However, hepatitis viruses, sex, the marital status, chronicity of hemodialysis, multiple hemodialysis, blood transfusion, and the crowding were not risk factors for CMV infections.

الهدف الرئيسي من هذه الدراسة هو تحديد الإنتشار المصلي للأجسام المضادة من النمط (gGI) والنمط (gMI) لفيروس مضخم الخلايا باستخدام اختبار الـ لايزا لـ 160 مريض يخضعون للإستشفاء الدموي و 40 شخص سليم ظاهرياً كضابط للختبار في ولاية الخرطوم تم اختيار المرضى الذين يخضعون للإستشفاء الدموي لهذه الدراسة من مستشفى ابن سينا التخصصي و مركز بحري لأمراض وزراعة الكلى و مستشفى أمدردمان التعليمي. من بين 160 مريض يخضعون للإستشفاء الدموي , 107 منهم كانوا ذكورا (65.6%) و 53 كانوا إناثا (33.1%) وتتراوح أعمارهم ما بين 14 إلى 90 سنة. وتشمل مجموعات المرضى الذين يخضعون للإستشفاء الدموي : 110 مريضاً لا يعانون من فيروسات إلتهاب الكبد الوبائي (68.8%) و 26 مريضاً يعانون من فيروس إلتهاب الكبد الوبائي (ب) (16.3%) و 24 مريضاً يعانون من فيروس إلتهاب الكبد الوبائي (ج) (15.0%). أما لأفراد ضابطي الاختبار , 19 منهم كانوا ذكوراً (47.0%) و 21 منهم كانوا إناثاً (53.0%) وتتراوح أعمارهم ما بين 14 إلى 73 سنة. وجد أن معدل إنتشار الأجسام المضادة لفيروس مضخم الخلايا كان عالياً بين المرضى الذين يخضعون للإستشفاء الدموي (98.12%) و المجموعة الضابط للختبار (100%) معا. وجد أن 157 مريضاً يخضعون للإستشفاء الدموي كانت لديهم أجسام مضادة من النمط (IgG) لفيروس مضخم الخلايا بنسبة 98.12% و 3 عينات فقط أعطت نتيجة سلبية بنسبة 1.88%. وكانت النسبة موزعة بين مجموعات المرضى الذين يخضعون للإستشفاء الدموي كالآتي : 108 مريضاً لا يعانون من فيروسات إلتهاب الكبد الوبائي (98.2%) و 26 مريضاً يعانون من فيروس إلتهاب الكبد الوبائي ب (100%) و 23 مريضاً يعانون من فيروس إلتهاب الكبد الوبائي (ج)

(95.5%) لديهم أجسام مضادة من النمط (gGI) للفيروس المضخم للخلايا. كما لا توجد أي فروقات ذات دلالة إحصائية بينهم (القيم الاحتمالية أكبر من 0.05). وجد أن: 105 من الذكور (98.13%) و 52 من الإناث (98.13%) كانت لديهم أجسام مضادة من النمط (gGI) لفيروس مضخم الخلايا, ولا توجد أي فروقات ذات دلالة إحصائية بينهما (القيم الاحتمالية أكبر من 0.05). بالمقارنة وجد أن كل أفراد المجموعة الضابطة (ذكوراً وإناثاً) لديهم أجسام مضادة من النمط (gGI) للفيروس المضخم للخلايا (100%). وجد أن 11 مريضاً يخضعون للإستشفاء الدموي (6.9%) كانت لديهم أجسام مضادة من النمط (IgM) منهم 5 مرضى لا يعانون من فيروسات إلتهاب الكبد الوبائي (45.5%) و 4 من

المرضى الذين لديهم فيروس التهاب الكبد الوبائي (ب) (36.4%) و 2 من المرضى الذين لديهم فيروس التهاب الكبد الوبائي (ج) (18.2%). ولا توجد فروقات ذات دلالة إحصائية بين المجموعات الثلاث (القيمة الاحتمالية أكبر من 0.05). كما وجد من هذه الدراسة أيضاً أن 8 من الذكور (72.7%) و 3 من الإناث (27.3%) كانت لديهم أجسام مضادة من النمط (IgM) ولا توجد بينهما فروقات ذات دلالة إحصائية (القيمة الاحتمالية أكبر من 0.05). وبالإضافة لذلك، وجد أن 11 فرد من المجموعة الضابطة منهم 4 ذكور بنسبة 36.4% و 7 إناث بنسبة 63.6% لديهم أجسام مضادة من النمط (MgI) ولا توجد بينهما فروقات ذات دلالة إحصائية (القيمة الاحتمالية أكبر من 0.05). زيادة على ذلك وجد من هذه الدراسة أن العمر هو عامل الخطورة الرئيسي للإصابة الأولية أو إصابة سابقة بفيروس مضخم الخلايا وعمليات نقل الدم هي عامل الخطورة للإصابة ثانوية أو إصابة متكررة بنفس الفيروس أو نشاط الفيروس مرة أخرى. كما لوحظ أيضاً أن: فيروسات التهاب الكبد الوبائي و الجنس و الحال الاجتماعية والفترة الزمنية للإستشفاء الدموي و عدد مرات الإستشفاء الدموي وعمليات نقل الدم و الإزدحام لا تمثل عوامل خطورة للإصابة بأمراض الفيروس المضخم للخلايا.
